Large Parietal Foramina—Noguera presents the report of a young adult who had a depression in the posterosuperior part of his head. A younger brother had the same abnormality, although the gap was very small. The rest of the family were normal. Roentgenograms of the patient's skull showed a defect in the posterior part of the cranial vault, a so-called parietal foramen. This is believed to be due to a disorder of ossification of the zones near the posterior fontanel. The abnormality is rare. As a rule it appears as two symmetrical defects in both posterosuperior regions of the cranial vault. The existence of only one large gap without an intermediate septum of ossification is still more rare. The abnormality is congenital and familial. The differential roentgenologic diagnosis of large parietal holes from Hand-Schüller-Christian syndrome, syphilis, secondary neoplasia, clidocranial dysostosis and circumscribed osteoporosis is based on the X-ray appearances. Large parietal defects manifest themselves as either one or two large gaps in the bony substance. When there are two defects, they are divided by a bony septum. The abnormality is more pronounced in the internal table of the skull. In all other cranial diseases the bone is thinned out, in some cases to a mere film, and the defect is small. In either case the lack of bone is less noticeable in the internal than in the external table of the skull.

- *Psychosis Observed in Treatment of Malaria by Combination of Atabrine and Plasmochin F. Ayala and G. Bravo—p. 70

Starvation, Edema, Plasma Proteins and Diuresis—Jimenez Diaz and his collaborators studied plasma proteins in their relation to the development of edema in undernourished persons. Tests were made at the time of hospitalization and during the treatment of the malnutrition. It was found that edema may exist in the presence of normal plasma proteins and fractions in the plasma, and that patients with severe hypoproteinemia and inversion of the albumin-globulin quotient may be free from edema. Thus it cannot be assumed that changes in the plasma protein level are the cause of the edema. It is evident, however, that patients with severe edema nearly always have a pronounced hypoproteinemia. Both symptoms are the result of deficient nutrition. There are, however, a number of other factors, such as emaciation, trophic disturbances in the capillary endothelium and excessive intake of fluid, which may play a part in the causation of edema.

Psychosis During Treatment of Malaria with a Combination of Atabrine and Plasmochin—Ayala and Bravo point out that the combination of atabrine and plasmochin in one preparation represents a simplified treatment of malaria. These two synthetic antimalarials appear to be strictly parasitotropic, but now that they have been used on a large scale it appears that they have a moderate affinity for certain organs. The study of this fact is of great importance in ascertaining possible contraindications to their combined administration. The author reports 4 cases in which a psychosis developed following the administration of the two substances. The drug apparently

has an elective tropism for the affective sphere. In the cases described the influence on the affectivity conducted to hyperthymia. The author observed minor degrees of affective alteration in other patients treated with the combination of atabrine and plasmochin. The psychosis is probably not caused by the malaria itself. The atabrine factor may be responsible, since it is known that atabrine exerts a direct toxic effect on the nervous system. Two of the patients had a predisposition to psychosis. The 4 cases described were observed among approximately 1,000 cases treated with the antimalarial combination of atabrine and plasmochin. If the cases of mild psychoaffective disturbances are included, the incidence would amount to 10 in 1,000. In a region in which endemic malaria has been increasing, many patients resort to the atabrine-plasmochin compound of their own accord. On the other hand, all those who develop mental disturbances are usually referred to the doctor by their alarmed families. The incidence of the psychosis is probably not more than 2 or 3 in 1,000.

- Fraumatic Shock A. Jurasz—p. 80
- Principles of Physical Diagnosis of Latent and Preclinical Pulmonary Lesions J. Skladal—p. 87
- *Pathogenesis of True Uremia A. Fidler—p. 92

Pathogenesis of True Uremia—Fidler points out that study at the University of Warsaw on the urinary excretion of nitrogen of well and uremic subjects, respectively, after feeding was approximately 63 and 73 per cent, thus in uremia its excretion is not diminished but rather increased. Further study revealed that the proteins of the serum in true uremia were physicochemically altered, making them more liable to break down. It appears that uremia is a disease of impaired protein metabolism and not of renal dysfunction. The changes in the serum protein might account for the rise in nonprotein nitrogen and the fall in the total protein in the blood. Study of the protein in the blood in chronic diseases of the kidney established (1) increased protein acidity, (2) a sudden accelerated diffusion of crude iron, (3) a change in clotting and (4) a change in the particle size of protein. The second and third of these changes serve as proof that protein is greatly inclined to split.

Massive Blood Transfusion for Acute Hemorrhage from Gunshot Wounds—Kaplan and Khanin emphasize the value of blood transfusion in war, in view of the fact that in past wars the majority of the wounded have died from hemorrhage rather than as a direct result of their injuries. In the Russian army blood transfusion has been extensively applied. While the usual dose recommended for a single transfusion is from 500 to 1,000 cc of blood, the authors have found this amount insufficient in many cases and have been obliged to increase it to 2,000 to 5,000 cc. Measures for arrest of the hemorrhage were applied simultaneously with blood transfusion in all cases. Gunshot wounds of the femoral vessels associated with profuse hemorrhage were especially favorably influenced by massive transfusions of preserved blood. In acute hemorrhage the blood loss is so rapid that compensating factors usually maintaining blood pressure close to normal levels have no chance to function. As a result, the rapid fall in blood pressure decreases vascular tone and impairs cardiac and respiratory functions. Large amounts of blood are required for transfusion in order not only to replace the lost blood and restore the oxidation processes of the organism but also to raise the blood pressure. Drip transfusion is ineffective in most cases of acute hemorrhage. Likewise artificial solutions are inadequate, since they cannot replace blood in its functional capacity.

Book Notices

War Injuries of the Chest Edited by H. Morriston Davies and Robert Coope. Cloth. Price \$2. Pp 131 with 36 illustrations. Baltimore: William Wood & Company, 1942.

The nine contributors to this small volume are members of a chest surgical unit in Britain. In chapter 1 are discussed anatomic and physiologic features necessary for clinical work on the chest. Chapter 3, though short, is exceedingly appropriate since it discusses general considerations, encouraging the physician to survey the injury analytically, so that proper evaluation of the injury and therapy may be attained as rapidly as possible.

A serious error is found on page 41, where the authors advise warning a patient in shock with blankets, hot water bottles and a shock cradle. For the past year or two the profession has realized the danger of heat in shock. However it is gratifying to note that oxygen therapy is strongly advocated.

The need for immediate treatment of patients with sucking wounds, tension pneumothorax, hemorrhage and "stove-in" chest is adequately emphasized. The fact that a patient can easily bleed to death in his pleural cavity is likewise properly emphasized and the method of treatment in such injuries is carefully and adequately described. Although all chest surgeons would agree to the advisability of removal of blood from the pleural cavity after twenty-four hours the danger of infection might be somewhat exaggerated over the impression usually held.

The danger of mediastinal emphysema with methods of relief are adequately discussed. The methods for taking care of the various types of wounds are likewise well discussed. The chapter on anesthesia is adequate, describing the various anesthetic agents and giving their advantages and disadvantages. The authors correctly warn against nitrous oxide because of the small percentage of oxygen possible during anesthesia. The danger of cyclopropane producing cardiac arrhythmia if opium derivatives are used in premedication is likewise described. The last chapter, on after-care is appropriate but somewhat short. The entire volume is well written and contains much valuable material, indicating that the contributors are experienced in their fields.

A Symposium on Respiratory Enzymes Addresses Given at an Institute Held at the University of Wisconsin, September 11-17, 1941. Cloth. Price \$3. Pp 281 with illustrations. Madison: University of Wisconsin Press, 1942.

This volume of twenty-nine papers covers the activities of the well attended and organized symposium on respiratory enzymes held at the University of Wisconsin in the summer of 1941. In his address of welcome President C. A. Dykstra gave evidence of a genuine interest in the problems and results of science and called attention to the international character of the contributors in this period of bitterest nationalism. The introductory lecture by Otto Meyerhof on intermediate carbohydrate metabolism presents the modern quantitative problems in a clear and masterly way. A lucid frank and critical treatment on oxidative mechanisms in animal tissues by Eric G. Ball is followed by a group of papers on the mechanism of hydrogen transport by K. A. C. Elliott, E. G. Ball and Fritz Lipmann, Kurt Stern and Erwin Haas and Elmer Stotz. Lipmann also discusses the "Pasteur effect" its inhibition and significance. Kurt Stern gives an inclusive and systematic treatment of oxidases, peroxidases and catalase. The chemistry and structure of nicotinamide nucleotide enzymes is well presented by Fritz Schlenk. T. R. Hogness treats the physical chemistry of the flavoproteins and the mechanism of action and characteristics of cytochrome C reductase. The chemistry of the cytochrome components and the physical chemistry biological action or function thereof is given by Elmer Stotz. The role of phosphoric acid is discussed from the point of view of phosphorylation of carbohydrates by Carl F. Cori and other aspects are treated briefly by H. M. Kalchor, Otto Meyerhof, M. J. Johnson and Fritz Lipmann.

E. A. Evans covers the general subject of metabolic cycles and decarboxylation in a detailed quantitative treatment. Philip P. Cohen presents a systematic treatment of transamination and

adds much from unpublished studies by him and his colleagues. Tumor respiration characteristics are discussed by K. A. C. Elliott, the question of phosphorylation in tumor metabolism by Van R. Potter, glycolysis in malignant liver tumors as compared with homologous adult or growing liver tissues by Dean Burk, and the correlation of the carcinogenicity of azo dyes to the effects of certain diamines on enzyme systems by C. J. Keisler. Bacterial respiration is reviewed by H. G. Wood and R. H. Burris from the point of view of the use of isotopes in experiments, by C. H. Werkman, E. S. Guzman Barron and P. W. Wilson on mechanisms for the complete oxidation of carbohydrates in aerobic bacteria and by F. F. Nord and P. W. Wilson on the comparison of the reactions in cell free enzyme systems with those in the intact cells. The symposium is closed by a series of brief discussions on animal tissue respiration under the chairmanship of C. A. Elvehjem. Ephraim Shorr, K. A. C. Elliott and Van R. Potter and Frederick Bernheim briefly discuss various aspects of the techniques used in studying tissue respiration. A. E. Axelrod presents a note on the action of calcium on the succinoxidase activity, E. S. Guzman Barron outlines pathways of carbohydrate metabolism, and Fredrick J. Stare raises the question of the role of citric acid in the citric acid cycle in muscle respiration. The book is well printed and contains thirteen interesting photographs of participants, taken during the meetings. It is an excellent and timely contribution to this difficult phase of biochemistry.

Annual Report of the Gorgas Memorial Laboratory 1942 Letter from the President Gorgas Memorial Institute of Tropical and Preventive Medicine Inc. Transmitting the Fifteenth Annual Report of the Gorgas Memorial Laboratory Covering the Fiscal Year 1942. 78th Congress 1st Session House Document No. 31. Paper. Pp 24. Washington D. C.: Government Printing Office, 1943.

A report of the physical and financial features of the institute with a summary of the more important scientific activities. Of special interest is the attempt to control malaria by monthly blood examinations and treatment for twelve consecutive years. It has been found that morbidity can be reduced materially, but there has been little effect on transmission. This is probably the most conclusive investigation ever attempted along this line. The widespread distribution of *Trypanosoma hippicum* in horses of Panama has been shown. It is very fatal to horses and mules but cattle suffer no effects although they harbor the organism. Vampire bats spread the infection and eventually succumb to its effects. The trypanosome infection in cattle caused by *Trypanosoma vivax* is a very serious disease and the probable vector was found to be the horn fly *Lyperosia irritans*. Investigations on the relationship of aquatic vegetation to the breeding of anopheline mosquitoes along the trans-Isthmian highway are under way. Mr. W. H. W. Komp has continued the intensive study on the anophelines of the Caribbean area and the first monograph has appeared. Important taxonomic studies on the Tabanidae are included. Intensive trials on insect repellents have been instituted. The results of immunologic investigations for improved diagnostic methods in malaria are given. For any one interested in tropical and parasitic diseases this annual report is extremely valuable, as it includes the results of investigation on numerous subjects from one of the most active outposts in this field.

Orthopedic Conditions at Birth Nursing Responsibilities. By Jessie L. Stevenson, R.N., Consultant in Orthopedic Nursing, National Organization for Public Health Nursing, New York. Paper. Grafts. Pp 80. New York: Joint Orthopedic Nursing Advisory Service of the National Organization for Public Health Nursing and the National League of Nursing Education, 1943.

This neatly printed pamphlet is one of a series being prepared and distributed by the Joint Orthopedic Nursing Advisory Service. No one else is better qualified to discuss this subject than is the author, Jessie L. Stevenson. This handbook was prepared for the purpose of assisting nurses in the early recognition of orthopedic conditions which can be present at birth and in the care of patients with these disabilities. The subjects covered include brachial birth palsy, cerebral palsy, congenital deformities of the extremities, torticollis and spina bifida. The material is well written and should be easily understood. Every general duty nurse who may be called on to care for an orthopedic patient should either know, or have readily available, information such as is offered in this small pamphlet.

Vascular Spasm: Experimental Studies. By Alexander John Nedzel, M.D., M.S., Associate Professor of Pathology, University of Illinois College of Medicine. Contribution from the Department of Pathology, Bacteriology and Public Health in the College of Medicine, Illinois Medical and Dental Monographs Vol. III, Nos. 3-4. Cloth. Price \$2.75. Paper. Price \$2.25. Pp. 151 with 161 illustrations. Urbana: University of Illinois Press, 1943.

In this valuable study, published in the monograph series of the University of Illinois, Nedzel presents the histopathologic background of stasis anoxia. The work provides a firm link between form and function and dysfunction, between the environmental impact of varied origin and the equally varied clinical symptomatology that may ultimately reflect the original disturbance.

The thesis that Nedzel has sought to establish finds its first clear statement in the hippocratic literature in the following terse sentences: "So in one place the blood stops in another it passes sluggishly in another more quickly. The progress of blood through the body proving irregular, all kinds of irregularities occur."

In our era Pawlinoff was apparently the first to recognize the role of stasis anoxia in inflammation though one fails to find reference to his work in Nedzel's monograph.

Nedzel's studies, which primarily are concerned with a histopathologic demonstration, are really holistic in character for he has approached the problem both from the physiologic and clinical side as well as from the morphologic. He first discusses the significance of localized vascular spasm then the more generalized shift in the blood mass that occurs between the splanchnic and peripheral beds associated with sympathectomy. The latter is illustrated by a series of original observations on temperature changes in various organs under varying conditions.

To simulate the exaggeration of organic rhythm which may find expression in the state of the vascular apparatus in both experimental and clinical conditions which, by individual predilection may be labeled sympathectomy vs. vagotomy or a relative alkalosis vs. a relative acidosis or an adrenal vs. a thyroid preponderance Nedzel has made use of single or repeated injections of pitressin and at varying time periods after such injections has excised the tissues and examined the microscopic picture.

The material selected for presentation in the monograph includes the endocardium, the stomach, the liver and kidneys and the central nervous system. While focused primarily on endocarditis ulcer of the stomach, nephritis and multiple sclerosis, the implications cover a wide latitude.

Nedzel first demonstrates that pressor episodes definitely change the endothelial cells at the impact surfaces of the endocardium. These reveal the characteristic histologic changes that are associated with stimulation, fatigue and necrobiosis, they become adhesive for fibrin, platelets and bacteria. With this as a background he demonstrates the mechanism of endocardial localization of bacteria as well as the processes of repair, i.e. the mechanisms underlying endocarditis. He then demonstrates the sequence when, with spasm, the surface of the stomach becomes unduly anoxic (particularly significant under conditions in which there is greater functional demand on the mucosal surface) and patches of necrosis occur. These, if coalescing or with repeated spasm or subject to gastric digestion, provide the background for ulcer formation. At necropsy such alterations are rather common, though often overlooked or disregarded. Because of the interrelation of kidney and liver damage with eclampsia, a flagrant disturbance of vascularization associated with undue spasm, Nedzel presents a brief but suggestive chapter illustrating changes that occur in these organs after pitressin injections. It is a field that should be extended. The final two chapters deal with alterations of the central nervous system and, while oriented about multiple sclerosis and the significance of change in vascular tone for bacterial localization in the central nervous system, the observations are of genuine importance for the neuropathologist.

For many years vascular dysfunction has been considered of significance for the symptom complex which we term multiple sclerosis. Putnam has already called attention to the thrombosis of the small blood vessels that can be observed. Nedzel's observations support the thesis that changes in the specific cells, with later alterations in the supporting components, follow in the wake of vascular change.

The title of the monograph must not obscure the recognition of the associated phase of undue dilatation of the vascular bed that follows vascular spasm. Spasm as well as the subsequent reaction of the tissue (stimulation, fatigue of the endothelium and so on) are associated with regional anoxia. The vaso dilatation, while physiologically a mechanism of reequilibration, may actually augment the disturbance of the oxidative balance particularly when associated with thrombosis.

Nedzel's studies contribute much to an understanding of the underlying mechanisms of disease, not only of the clinically acute forms, but of the so-called wear and tear diseases, when the insidious breakdown of vascular supply and tissue demand is followed by erosion of the parenchyma and the overgrowth of connective tissue cells. It is in this domain that knowledge of repetitive insults by weather and emotion, undue stimulation and fatigue, minor trauma and infection—all of which are of the kind simulated in Nedzel's experiment—becomes of great importance and Nedzel's studies are of particular value here. The text is concise, the illustrations are well selected and unusually good. An adequate bibliography is appended, but an index has not been provided. The contribution is one of the most valuable of the interesting series published by the University of Illinois not only for the pathologist, but for the physician interested in the mechanism of the organic breakdown.

Creatine and Creatinine Metabolism. By Howard H. Beard, Ph.D., Professor and Director of the Department of Biochemistry, School of Medicine, Louisiana State University, New Orleans. Cloth. Price \$1. Pp. 176. Brooklyn: Chemical Publishing Company, Inc., 1943.

This book presents a survey of the progress made in the field of creatine and creatinine metabolism during the last fifteen years since the publication of Hunter's classic monograph on this subject. The author includes, where possible, applications of experimental studies to human metabolism and to certain diseases of man. Detailed instructions are given for the determination of creatine and creatinine in body tissues and fluids by standard procedures, and the newer specific enzymatic methods are briefly discussed.

The question of the precursors of creatine and creatinine in the organism is discussed in detail, the author defending at length his theory that creatine is formed primarily from aminoacetic acid and urea, with subsequent methylation, rather than from aminoacetic acid and arginine as is generally believed by other investigators. The author's finding of an apparent stimulation of creatine formation and creatinine excretion by a large number of widely dissimilar substances is puzzling. Especially is this true in the case of his studies on the methylation of glycocyamine to form creatine, the results indicating that such diverse substances as methyl alcohol, methyl amine and methyl purines can serve as methyl donors. The changes observed in creatine-creatinine metabolism following the administration of various vitamins and hormones are likewise difficult to understand.

Some of the suggested applications of experimental studies to the treatment of certain human diseases appear unwarranted because of a lack of sufficient undisputed supporting evidence. For example, the preponderance of evidence today indicates that in contrast to the observations of the author, aminoacetic acid and gelatin have no consistent value in increasing muscular work output in human subjects. Likewise the suggestions that aminoacetic acid is beneficial in the treatment of certain myopathies, heart diseases, allergy, toxemias of pregnancy and diseases of the eye appear at least premature in view of a lack of sufficient experimental evidence.

The most startling portion of the book is the final chapter dealing with the relation of amino acids, amines and guanidine bases to tumor growth and regression. From studies on rats with transplanted sarcomas the author has graded the known amino acids (except tyrosine) with respect to their abilities to stop the growth of tumors or to cause their disappearance. The author concludes (p. 309) that "creatine and its derivatives or precursors in the body, as well as creatinine in one instance will cause tumors to disappear."

This book will be found of value chiefly for its extensive bibliography on creatine-creatinine metabolism and for bringing to attention many new and puzzling claims for these two important substances and their alleged precursors.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THE NAME WILL BE OMITTED ON REQUEST.

TREATMENT OF TETANUS EXPOSED PATIENT PREVIOUSLY IMMUNIZED WITH TOXOID

To the Editor—If a patient is given tetanus toxoid for active immunization what does one do if an injury which would ordinarily require antitoxin occurs six months after the toxoid, one year after the toxoid, two years after the toxoid, three years after the toxoid, eight years after the toxoid, fifteen years after the toxoid? Does the original toxoid give lasting immunity without any further stimulating doses? If not, will semiannual or annual stimulating doses produce that effect? In short, has the use of toxoid now made it unnecessary to use the antitoxic serum?

Louis V. Blum, M.D., Baltimore

ANSWER—The question of whether to depend on a given type of on a previous active immunization or to administer a prophylactic dose of tetanus antitoxin is a matter for surgical judgment. Certain general principles, however, can be laid down for guidance. It is now generally agreed that administration of two doses of 1 cc. each of alum precipitated toxoid from one to six months apart will produce basic immunity. After such treatment the reactivity of the person is enormously increased so that a subsequent boosting dose of toxoid given three or six months later will increase the antitoxic content of the blood from twenty to fifty times, giving an immunity of a higher degree and longer duration than that which existed before. The duration of immunity has never been definitely established. It may vary from as short a period as three months to a lifetime. A series of three doses in the course of one year will generally speaking give an immunity which will last two or more years. Because of the great individual variation in responses it is always advisable in the face of definite exposure to give a still further dose of toxoid with the view to rapid stimulation of additional antibody formation. It must, however, be borne in mind that formation of antibodies consumes time. For this reason it is always good judgment in the presence of badly macerated tissues to give immediately a prophylactic dose of antitoxin serum while waiting for the effect of the boosting dose of the toxoid. To particularize, it may be stated that the original toxoid immunization should not be relied on as furnishing lasting immunity without further stimulating doses. Semiannual or annual stimulating doses as suggested in the query will certainly produce that effect. One certainly would resort to additional doses after eight and fifteen years. There will be occasions when it will be necessary and wise to employ the antitoxin serum in addition to the toxoid immunization.

GLASSES NOT NEEDED ON VACATION

To the Editor—A married woman aged 32 has been wearing glasses for ten years. Last summer while vacationing in the Adirondack Mountains in New York she noticed that she was able to do without her glasses completely. However, on returning to her home in New Jersey she was unable to get along without them. I have since learned that her mother had exactly the same experience many years ago. My patient did not know this at the time. Thank you for any explanation.

Lieutenant M. C. A. U. S.

ANSWER—It is not uncommon to hear of patients who get along quite well without glasses when they are on vacations and not using their eyes consistently but who do require glasses when they are doing their regular work, even if this is doing housework. In the case reported the extent of the refractive error is not stated. This would have indicated how much of a handicap the woman is overcoming in going without her glasses. It is quite likely that she had a rather slight refractive error and needed glasses only under conditions of strain. Aside from the relief of this strain during a vacation any other explanation is doubtful.

VITAMIN K AND DENTAL CARIES

To the Editor—I have recently read a brief statement about the use of vitamin K in the prevention of dental caries. Have you any information as to indications, dosage recommended and results thus far reported?

Louise C. Gloeckner, M.D., Conshohocken, Pa.

ANSWER—It has been found on the basis of *in vitro* and *in vivo* experiments that vitamin K will materially inhibit acid formation in the mouth. However, these studies are still in an experimental stage. The evidence on hand is insufficient to indicate the use of vitamin K as a therapeutic measure for dental caries.

THROMBOPHLEBITIS AND TRANSFUSION OF COMPATIBLE BLOOD

To the Editor—I recently attended a white woman aged 43 who had an intrauterine leiomyoma and who had had a number of repeated and severe hemorrhages before seeing me. Her past medical history revealed that she had suffered from right heart failure about one and a half years before. After a period of time in bed and with medications she was able to live a somewhat restricted life. Some ten years previous to this she had an attack of inflammatory rheumatism after the birth of her last child. Physical examination revealed her to be a short obese woman with a systolic murmur over the base of the heart. Blood pressure was 112/72. Laboratory examinations showed a hemoglobin of 33 per cent with 2,700,000 red blood cells and 3,600 white blood cells. The differential count showed 66 per cent polymorphonuclears, 26 per cent lymphocytes, 2 per cent monocytes, 4 per cent eosinophils and 2 per cent basophils. The blood smear was showing a definite anisocytosis and some polychromasia. She was sent to the hospital and because of her poor condition a transfusion was performed. She had a type 2 blood and a donor with type 2 blood was used for the transfusion. On cross agglutination there was no reaction. There was no immediate or delayed reaction following the transfusion. Two days later a biopsy was made of the tumor without the use of anesthesia with the exception of morphine. This proved to be a benign leiomyoma. To prevent further bleeding she remained in bed with the foot of the bed elevated. She responded well and her general condition became much improved. Ten days after the transfusion she developed typical thrombophlebitis first in one leg and then in the other. She was subsequently told by another physician that the thrombophlebitis was due to the transfusion given her from a type 2 donor. He emphasized that the thrombophlebitis was due to her receiving type 2 blood when she was of the same type. I am unable to find any verification of this statement in any available literature. I should like to know if there is any possibility of this complication arising following a transfusion given to a recipient whose blood is type 2 from a donor with the same type of blood. If this is true, what procedure should be followed in transfusing a recipient with type 2 blood?

M.D., Minnesota

ANSWER—It is common knowledge that thrombophlebitis is a not infrequent postoperative complication particularly in debilitated patients with sluggish circulation. It is significant that the patient gives a history of rheumatic fever with an attack of right heart failure one and a half years before the operation and that at the time of the operation there were signs of mitral insufficiency. To attribute the thrombophlebitis to a transfusion of blood of the correct group given ten days previously is absurd. Incidentally, instead of type 2 the designation group A should be used in conformity with the practice of the armed forces, the Red Cross and all progressive hospitals.

TREATMENT OF UTERINE CANCER IN AGED

To the Editor—A woman aged 82 has been bleeding or spotting for six months to a year. One week ago she had a severe hemorrhage. She was taken to the hospital and under cyclopropane an examination was made. The uterus was not large, the cervix was thin and curettage for diagnosis gave the feeling of polyps, not of cancer. The pathologic diagnosis came back adenocarcinoma grade 2 of the fundus uteri. Radium was applied to the inside of the fundus and left for seventy-two hours. Since its removal the bleeding has nearly stopped. Considering the age of 82, a normal blood count, a normal urine and a well preserved person both physically and mentally, what is the best type of treatment to recommend? Should treatment be conservative or only one course be given, that of a radical nature?

M.D., Indiana

ANSWER—A patient of advanced age with a cancer of the body of the uterus should be treated with radiation. If radium is employed it should be inserted into the uterine cavity in sufficient amount to come in contact with the entire endometrial surface. The amount of radiation either at one sitting or interruptedly over a period of a few weeks is usually a total of at least 3,500 milligram hours. After several months another treatment preferably a somewhat smaller amount may be given with advantage.

The curettage may have been necessary to confirm the diagnosis but curettage in such cases should be avoided whenever possible. It required it should be performed gently and not more thoroughly than necessary to confirm the diagnosis. With curettage there is always a hazard of cancerous spill through the fallopian tubes into the abdominal cavity or extension through the lymphatics and venous sinuses into the broad ligaments and beyond.

High voltage roentgen therapy is a helpful adjunct to intrauterine irradiation in cases in which there is likelihood of extension or the growth beyond the confines of the uterus.

Although radiation for cancer should ordinarily be given as intensively as possible and over a relatively short period of time with an elderly patient it is preferable to be more cautious, interrupted short applications of radium and less frequent x-radiation lessen the morbidity and decrease the hazard.

OCHRONOSIS AND ALKAPTONUREA

To the Editor—I have under my care at the present time a white woman aged 85 in whom the diagnosis of ochronosis has been made because of (1) pigmentation of the ears and sclerotics, (2) urine that darkened considerably on exposure or addition of alkalis and (3) osteoarthritis of the knee joints and spine with the latter showing all the changes described by Pomeranz. A study of the urine revealed the presence of both homogentisic acid and melanin. She has no evidence of melanosis. Have any cases ever been described with the findings of both melanin and homogentisic acid in the urine? Morgan Y. Swirsky, M.D., New York

ANSWER—Certainly the diagnosis of ochronosis seems justifiable in view of the evidence as listed in the question. In the article by Oppenheimer and Kline there is a tabulation of all reported cases, and 1 of these cases presented melanuria "and probably alkaptonuria." A partial bibliography relating to ochronosis:

CYST OF POPLITEAL BURSA

To the Editor—Oct. 7, 1940 a patient had a large painful popliteal bursa excised from the left leg. He made an uneventful recovery. Now the insurance carrier writes that he has presented himself to another physician for treatment who tells him that evidently all of the tumor was not removed in the previous operation and he should have another operation as soon as possible. I have never had any experience with a recurrence of this type of bursa and can find nothing in the literature on the subject that would give me any clue. Can you give me any information on this?

M.D., Wisconsin

ANSWER—The pathologic nature of a cyst of the popliteal bursa is quite similar to that of an ordinary ganglion. If all of the cyst is removed, including the stalk, which is nearly always present and frequently extends down between the condyles of the femur posteriorly to the joint capsule and may be patent, communicating with the joint, recurrences are unlikely to occur.

If portions of the wall of the cyst including the lining are left behind, just as is true in the case of an incomplete excision of a ganglion, recurrences will be fairly common.

This condition was described by Baker in the reports to St. Bartholomew's Hospital in London, volume 13, page 245, and volume 21, page 177. It is sometimes called Baker's cyst.

MANUAL LABOR FOLLOWING NEPHRECTOMY

To the Editor—Do you consider a man who has had a nephrectomy (hydro-nephrotic infected kidney with stone found at operation, carcinoma of ureter was preoperative diagnosis) and completely recovered therefrom able to do hard manual labor? If not, why? If so, why? A man aged 51 and such an operation. As conditions which caused the nephrectomy remain uncorrected, he is liable to further renal damage which might possibly disable him.

M.D., California

ANSWER—A man who has had a nephrectomy for a hydro-nephrotic infected kidney with stone is probably able to do hard manual labor provided his urinary tract is now completely sterile, he has no evidence of stone remaining in the urinary tract and he was used to doing hard manual labor before his present sickness. There is no reason why a man with one sound kidney cannot carry on as before as far as his kidney function is concerned, as one kidney affords more than adequate function for the body needs and, as far as is known, hard work does not adversely affect its performance if the body is cared for satisfactorily in other ways by conservative living.

It is, of course, important to be sure that this patient has no infection remaining in the urine or in the lower genital tract.

SUCTION METHOD OF CATARACT EXTRACTION

To the Editor—Could you give me information on the Dmitry suction disk for intracapsular cataract extractions? Please let me know whether you think it is an efficient instrument for intracapsular cataract extractions by the suction method.

James S. Davis, M.D., Marion, Ill.

ANSWER—The Dmitry disk is a simple and effective instrument for applying suction to the lens capsule. There are certain objections to the suction method of cataract extraction, one of which is that the incision must be quite large and is made to gaps more widely during removal of the lens with any suction apparatus than with the use of forceps. However, in the intumescent stage of cataract the suction method allows intracapsular extraction where other methods fail and in such cases the Dmitry apparatus has proved of definite value. It is, in the opinion of certain ophthalmologists, equal to more elaborate instruments for the suction method.

SOYBEAN MILK AND COW AND HUMAN MILK

To the Editor—Would you kindly tell me the comparison between soybean milk and cow's milk. Could soybean milk be used in place of cow's milk for human infants? How do the proteins, fats and carbohydrates in soybeans compare with those in human milk? I understand that in China and Japan they have no cow's milk and they use soybean milk in its place.

James H. Rosecrans, M.D., Hoboken, N. J.

ANSWER—The soybean contains 40 per cent protein, 20 per cent fat and very little carbohydrate. The protein is vegetable protein high in aminoacetic acid and is said to give as normal a growth as the animal protein casein contained in cow's milk. Soybean milk as compared to cow's milk is deficient in fats, carbohydrate, minerals and vitamins. This fault is overcome by several commercial products in which olive oil, arrowroot starch, maltose and dextrose, and salts of dicalcium phosphate, and sodium chloride are added. Such a mixture in the form of a powder when added to water is similar to cow's milk in percentage content and not like human milk. The green and yellow types of soybean have long been a preferred artificial feeding of Oriental infants. It has been used in this country for some time as a food for infants allergic to animal protein.

COCAINE-PHENOL MIXTURE FOR DRUM MEMBRANE ANALGESIA

To the Editor—Is there danger from cocaine reaction in using cocaine, menthol and phenol in equal proportions for local ear anesthesia? I have used it in many cases and have never had trouble with it even in small children.

Harold L. Snow, M.D., San Pedro, Calif.

ANSWER—Topical application of this mixture to the drum membrane to make paracentesis less painful has been practiced for many years. A rather careful search of the literature has not discovered any reports of a "cocaine reaction" following the procedure. Absorption of drugs applied to the intact skin is minimal. Failure of this method in some cases to abolish the pain of paracentesis is evidence of this fact.

Probably phenol is the active constituent of the mixture when successful analgesia results from its application.

VACCINES AND TUBERCULOSIS

To the Editor—In reply to a question concerning vaccines for tuberculosis which appeared in *The Journal*, April 24, 1943, page 1419, mention is made of the work carried out by Dr. E. A. Watson, and he is suggested as a source of BCG vaccine. Dr. Watson did some work with BCG a number of years ago, but I believe the only Canadian source of vaccine at the present time is Dr. Armand Frappier, University of Montreal, Montreal, Quebec. Dr. Frappier learned the technique of preparing BCG from a representative of Calmette's laboratory, and his work was for some time supported financially by the National Research Council of Canada. In the last few years it has been taken over by the department of health of the province of Quebec. Dr. Frappier's vaccine has been used quite extensively in Montreal and elsewhere in the province of Quebec for the vaccination of children and in the last few years has been supplied to Dr. R. G. Ferguson of Saskatchewan who has vaccinated a substantial number of Indian children and hospital employees in that province. In the reply to your inquiry mention was made of a number of early articles on BCG, but there is no reference to what is perhaps the most important paper on the use of BCG in Canada. I refer to a paper by J. W. Hopkins in the *American Review of Tuberculosis* for May 1941, page 581. It gives a brief history of what is perhaps a unique experiment in the vaccination of children with BCG and includes a statistical analysis of the results obtained. I may add that in both mortality and morbidity the vaccinated children showed a favorable effect. Results since that time add weight to the tentative conclusion and it is hoped in a few years to make a further complete analysis of the results of this experiment and publish the findings.

THE NEARER CAUSES OF CANCER

PEYTON ROUS, M.D.
NEW YORK

More than twenty-five years have passed since man first learned how to call forth cancer for his purposes. Throughout the centuries he has seen it follow on exposure to sunlight and watched it arise in old scars, yet only so recently has he felt any need to produce it. By 1915 though the risk had become inevitable and insistent to get on further with the cancer problem to grapple with immediate causes the searcher had to study the disease at its origin. Now he can call it forth in any one of many ways and follow its emergence from hour to hour as he chooses. Yet still he is like an Aladdin who calls forth a genie that he does not understand, much less control, and the meetings of societies for cancer research are like gatherings of Aladdins with great talk of how most surely to evoke the genie and of how soonest and from what sort of bottles, and of why the genie come and, having come behave as they do. The present lecture is concerned with these last questions.

Something should be said in preliminary on the place of cancer among the tumors. It is that of an extreme instance no more. The distinction necessarily made in practice between benign and malignant growths, though vital to the patient is not expressive of any basic cleavage save in the case of the teratomas and other self-limited developmental anomalies that manifestly are not true neoplasms. In the days when only human tumors were studied it was noted that some growths in the benign category it let alone would enlarge until they killed, and instances were now and then encountered, e. g. adenomas of the thyroid gland which though orderly and seemingly harmless gave metastases.¹ Later, when the transplantation of animal tumors was undertaken some spontaneous benign growths were successfully transferred and these proved able to grow indefinitely, killing host after implanted host by the sheer bulk of their demands, the Ehrlich chondroma for example. Now with experimental carcinogenesis a busy, laboratory occupation the fact has come to light that the agents which call forth carcinomas and sarcomas evoke as well a wide array of neoplasms from the most malignant to some which have so little initiative as to require aid if they are to exist at all.² Here is more evidence that the benign tumors and the cancers are only individual expressions of a single strongly characterized neoplastic principle.

Deviations from this principle Kaposi's sarcoma for example, are few and significantly rare. So well do present day investigators realize the essential unity of the tumor problem that they undertake work with experimentally induced hepatomas, papillomas, adenomas and other benign growths in the sure belief that what these may tell will contribute somehow to the understanding of carcinomas and sarcomas. Indeed they apply the term carcinogenic as matter of course to agents which not infrequently call forth a horde of benign neoplasms for every ultimate one that is malignant and they look on such neoplasms as indicators of carcinogenic power. It is often and truly said that the tumors as a class represent a multiplicity of diseases, but this is because the character of each individual growth is largely determined by the specializations and inherent capabilities of the cells from which it has sprung as result of neoplastic change. When this change occurs elements which had appeared identical in form and function may give rise to widely differing tumors, their possibilities gaining different exploitation. Yet the neoplastic principle implicit in them is no less single because of the variety of its manifestations.

Pathologists have realized for a long time that normal cells while functioning may behave for a brief while as if neoplastic, those of the chorion for example. In 1906 it was found that the intradermal injection of oily solutions of certain dyes, notably scarlet R and sudan III was frequently followed by local downgrowths of the epidermis in narrow strands which penetrated amid the corium and sometimes entered lymph vessels giving a picture which wholly resembled anaplastic squamous cell carcinomatosis except for the droplets of stained oil in the tissue.³ The malignant activities continued only so long though as dye was present, the epidermis eventually forming an orderly layer around the decolorized oil the stimulus experimentally provided had run out, but a further temporary downgrowth could be obtained by repeating the injection. These phenomena not only made it plain that ordinary cells are able to behave as if cancerous in response to extraneous influences but they justified the inference—though this was not made at the time—that an actuating cause for tumors need only work on capabilities which cells innately possess, and go along with them as they multiply in response to its presence. This is not to say that a tumor cell can be regarded as merely a stimulated normal cell whatever causes it to become neoplastic often renders it unhealthy and frequently induces metaplasia. All in all it now seems superfluous and a bit grandiose to assume as has been easy in the past that the cause for the cancerous process is a secret bound up with life itself. There is no need even to sup-

pose that tumor cells are the outcome of some inherent, fundamental cell change, though this is a favorite supposition.

On scrutinizing a representative list of the agents which act in such a way on tissues that tumors result (table 1), one sees straight off that most of them cannot be the actuating causes of the growths they call forth. The point need not be labored for the mechanical and physical agents—gallstones, ill fitting horse harness, the roentgen rays, heat or freezing, and so forth. These may do their injury and be gone months or years before tumors develop. And animal parasites, tubercle bacilli for instance, *Bilharzia* and the larvae of the worm *Cysticercus* (which become encysted in rat livers with the consequence that sarcomas arise from the cyst wall) are rapidly left behind as the tumors enlarge that they have provoked. Plainly in all such cases one must look to some factor accompanying the cells, or to an intrinsic alteration in them, in accounting for their new state.

Chemical agents of widely diverse sorts will give rise to tumors on test. By painting the skin of mice with weak hydrochloric acid, potassium hydroxide or tar made from human skin it is possible to evoke carcinomas, and the injection of lard or olive oil into the subcutaneous tissues sometimes results in sarcomas, but

TABLE 1—Diversity of the Carcinogenic Agents

Mechanical Irritants (e. g. gallstones, ill fitting, bridles or horse harness)		
Röntgen rays	Freezing and thawing	
Radium	Heat (burns)	
Ultraviolet light		
Aniline dyes	Extracts of cancerous organs	
Coal tar	Tar from animal tissues	
Synthetic hydrocarbons	Animal fats	
Other complex pure substances	Dextrose	
Hormones (estrogens, pituitary hormone)	Potassium hydroxide	
	Hydrochloric acid	
Parasites (e. g. tubercle bacilli, <i>Cysticercus</i> larvae, <i>Bilharzia</i>)		
Viruses		

all this has no likeness to natural conditions. Such complex materials as tar may contain however something carcinogenic which the body is capable of manufacturing, and actually a hydrocarbon of pronounced carcinogenicity, methylcholanthrene, has been synthesized, which is nearly related chemically to the bile acids.⁴ Furthermore, certain substances normally made by the organism and functioning for it in important ways, the estrogenic hormones in special,⁵ have proved capable of bringing about tissue changes which have tumor formation as their consequence, and extracts of human cancers or of the organs of cancerous individuals will call forth tumors now and again when brought to bear on the tissues of mice.⁶ Some of the polycyclic hydrocarbons do so with striking sureness and rapidity, papillomas and cancers appearing on the skin within a couple of months, and there are viruses which produce growths in chickens and rabbits within a few days after inoculation. In the latter instances the gap between cause and effect would appear on first sight to have

been significantly narrowed. To learn whether this is really the case has become a prime duty of cancer workers.

The pathologist Ribbert, who made rewarding studies of the first stages of human carcinomatosis, used to say that the cancer problem would finally be solved through the utilization of growths arising from the skin, since there one can follow events most closely. The first event after a chemical carcinogen is painted on the skin has proved to be in nearly every instance a non-neoplastic cell disturbance which has many of the features of a low grade, chronic inflammation of ordinary sort and might be taken for such except that out of it tumors come. Observers agree that the neoplastic change is no mere exaggeration of the disturbance but something discontinuous in character, new, strange, abrupt and irreversible, and it does not take place everywhere throughout the expanse of abnormal tissue but only here or there, often at several or many spots, as a seemingly punctate alteration. In microscopic sections from interior organs submitted to the carcinogens one can usually perceive a similar course of events, first a tissue disorder throughout the implicated region, entailing cell proliferation ordinarily, and then a starting forth of growths at one point or another. The happenings are much the same when true tumors appear on the basis of developmental anomalies, the latter being carcinogenic in the sense that they provide a terrain suited to neoplastic change (von Recklinghausen's disease for example, intestinal polyposis, the retinal disturbance preliminary to malignant gliomas⁷). The action of the sex hormones is more various. When contributing to tumor formation they may merely stimulate gland tissue to develop, in this way providing the cells on which other carcinogenic agents can act, or if supplied in excess they may themselves produce the tissue disorder out of which tumors come. And they may do still more: they may urge neoplastic cells on, so that they multiply into tumors, as in the case of those prostatic cancers which retrogress after orchectomy.⁸ Some times they act in all these ways. Little has been learned as yet of the mode of action of the carcinogenic extracts of normal and cancerous tissues,⁹ but this little would seem to indicate that it is of the ordinary sort, the extracts producing a chronic disturbance on the basis of which neoplastic change may or may not supervene after a considerable lapse of time. The only carcinogenic agents which are known to produce tumors by direct action are the neoplastic viruses. And prior to any discussion of how these act it is necessary to ask whether they engender true tumors.

The growths which have been traced to the action of viruses are few in comparison with the multitude of those for which no cause is known, yet their number and variety are not inconsiderable. They are notably frequent in the domestic fowl, and study has proved them to be typical tumors not only in morphology and behavior but in collateral respects, notably in incidence.¹⁰

They occur hither and yon like human tumors, their natural distribution seeming all against any relationship of one to another. Sarcomas in wide variety, fibromas, myxomas, osteomas, chondromas, in endotheliomas and several kinds of leukemias have all proved due to viruses with carcinomas still to be investigated, and workers in this field have lately concluded that every spontaneous chicken tumor will yield a causative virus if only it can be successfully transplanted and its vigor enhanced by passage in a series of favorable hosts.¹¹

Within the last few years kidney tumors due to a virus have been discovered in the swamp frog (*Rana pipiens*).¹² The growths originate from the epithelium of the renal tubules, and they range histologically from orderly adenomas to invasive adenocarcinomas which metastasize by means of cell emboli. They can be transplanted and they resemble the classic tumors histologically except in one respect—the cell nuclei contain large inclusions in most instances, such as a virus may cause. Inclusions of this sort are rare in human neoplasms though they do occur in certain growths of the central nervous system.¹³ The more orderly of the frog tumors sometimes show no inclusions, then appearing wholly typical, a fact not without significance as bearing on cell-virus relationships.

These tumors of chickens and frogs seem distant from the human problem. But recently a virus has been discovered¹⁴ in the huge keratinized horns and warty excrescences—epidermal papillomas—which western cottontail rabbits sometimes carry on their skin and the growths have been found to exhibit all of the immediate traits which characterize tumors as a class.¹⁵ When the virus is rubbed into the scarified skin of domestic rabbits it gives rise to papillomas which often grow with remarkable vigor and become carcinomatous within a few months.¹⁶ Indeed in its power to bring on rabbit cancer rapidly the virus outstrips all the other carcinogenic agents known.

The papillomas are in general well tolerated by the cottontails which are their native hosts but they may temporarily behave as if malignant, simulating squamous cell carcinomas histologically, invading and replacing the muscle beneath them and penetrating into the blood and lymph vessels and along the latter to the nearest lymph node, like certain carcinomas of the human mammary gland,¹⁷ yet even such growths after a while take on the ordinary keratinizing, papillomatous form and no longer threaten the life of the host. Genuine cancer does occur though as a late and occasional event.¹⁸ The

papillomas are often multiple and the derivative malignant tumors may be multiple too, cottontails have been trapped which carried squamous cell carcinomas in every stage of development as many as sixteen on the skin of a single rabbit each derived or deriving from a separate papilloma. Metastases to the lymph nodes and lungs are frequent.

The papillomas resulting from the inoculation of domestic rabbits—to which the virus is foreign—may attain immense size before cancer develops and bring about death through sepsis and hemorrhage. If the virus-infected cells are inadvertently dislodged or purposely injected into the blood stream, they survive in the lung tissue to which they are transported and form secondary nodules there by intrinsic cell proliferation induced pulmonary metastases as one might say. Always as the papilloma grows progressively—for sometimes it dwindles and disappears—cancer ultimately develops and at many points in the proliferating mass it the animal lives long enough. But the malignant change occurs only after nearly four months at the earliest and usually half a year or more must have elapsed. How the cancers come about will be discussed further on. Here only the immediate effect of the virus will be considered and thus regularly finds expression in papillomas.

On looking into the relation of the neoplastic viruses to the tumors they engender one perceives several profound differences from the other known carcinogens. The viruses do not act obliquely or at any remove, but they directly change the cells they infect into neoplastic cells without giving rise to any intermediate tissue disturbance. What is more they accompany the changed cells as these multiply into tumors increase in amount as the latter enlarge and can usually be recovered from the proliferating tissue in a state to produce growths of the same kind in fresh hosts. When they cannot be got, their presence is demonstrable by serologic tests, since they induce the formation of specific antibodies, these appearing in the blood of the hosts. They maintain a working relationship with the cells they have infected continually urge the latter to neoplastic activities and, in short, do precisely what extraneous agents would have to do judging from the observed effects of scharlach R if they functioned as the actuating causes of tumors. None of this holds true of any of the other carcinogens, those already discussed. Some disappear from the tissues before the neoplastic process begins and the others soon afterward. Even the most potent of the chemical agents is diluted out as the tumors due to it increase in bulk, and soon no trace of it can any longer be demonstrated. True extracts of human carcinomas will now and again give rise to tumors in mice. But so too, though less frequently, will extracts of normal tissues, while furthermore the mouse tumors which these materials induce (sarcomas, epidermal papillomas which may become cancerous secondarily) are of the kinds which follow also on the action of various agents that can scarcely have a near relationship to natural neoplastic processes. As already stated, the introduction of foreign fats, e.g. olive oil or lard or the repeated injection of sugar will cause sarcomas to arise in mice (though mouse fat will not), and the repeated application of oleic acid to the skin of these animals¹⁹ and of benzene to

rabbit skin will cause papillomas to appear²⁰. Yet though these facts make against the possibility that the extractives from human carcinomas are the actuating causes of tumors, this does not mean that the finding is devoid of significance. On the contrary, it strongly implies that the disordered body may now and again manufacture substances which so disturb the tissues that tumors result.

TABLE 2—Examples of Summated or Substituted Carcinogenic Action

Carcinogens	Authority
Beta radiation—benzpyrene	Mottram
Benzpyrene—X rays	Maynord and Parsons
X rays—diben anthracene	Maynord and Parsons
Estrogen—benzpyrene	Mottram, Gilmore, Perry and Glinton

Not only do the viruses render normal cells neoplastic when inoculated experimentally and maintain a partnership with them subsequently, but everything goes to show that they function in this way under natural conditions. All of them were originally procured from "spontaneous" tumors of one sort or another, and on subsequent inoculation all have given rise to growths essentially like those from which they were first obtained: a virus derived from myxomas producing only myxomas, an endothelioma virus endotheliomas, and so on. In this specificity of effect they are sharply different from the carcinoma extracts just discussed. Their determining influence on the kind of tumor they produce is most striking and it sometimes results in growths of such highly complex character as could only result one might have supposed from innate cell peculiarities. They are enabled to produce these growths (for example osteochondrosarcomas, intra-canalicular sarcomas) because they influence cells of certain kinds only and exploit their latent capabilities. Not infrequently they injure the elements they infect, with result in cytologic changes indicative of damage like those occurring in the tumors due to causes as yet unknown.

The other carcinogenic agents thus far considered determine the type of tumor they call forth only so far as they have affinities for certain organs or tissues, which in consequence bear the brunt of their effect, and even when these affinities are pronounced, tumors of several kinds usually result from their action. The carcinogenic azo dyes, which have attracted great attention of late as affecting the liver in special, elicit not only benign and malignant hepatomas and cholangiomas but reticuloendotheliomas as well, and sarcomas of the connective tissue, pulmonary tumors and hemangiomas, mostly amid adipose tissue,²¹ and sometimes papillomas of the stomach and urinary bladder. The estrogens, besides inducing growths in the glands they specifically influence, may call forth spindle cell sarcomas or lymphomas when injected subcutaneously.²² There would seem to be no reason why a chemical carcinogen should not be so selective as to act on only one sort of cell and in some unique way, with result in a neoplasm distinctive of its action, but thus far none has been discovered. Certain of the polycyclic hydrocarbons, notably benzpyrene and methylcholanthrene, are pancarcinogens, capable of bringing about neoplastic changes in

cells of so many kinds that as yet no limit has been reached in this respect. They produce papillomas and carcinomas of the skin, sarcomas of all sorts and at many situations, rhabdomyomas and leiomyomas, bone tumors, lymphomas, tumors of the liver, lung, breast and uterine tissues, the galaxy of brain tumors, and many growths besides, as also leukemias, according to the species and breed of animal and the kind of tissue submitted to their influence. As might be expected from this lack of specificity, it has been found that some carcinogens of wholly unrelated sorts very frequently call forth tumors of identical kind, and that furthermore one of them may substitute for, or reinforce the action of another in so doing (table 2).

These facts fall in with the evidence already cited as showing that the generality of carcinogens do not actually start off a process with which they have no further essential relation. And that this is the true state of affairs is made still clearer by the effects of such agents when acting on animals of different species, or individuals of a single species but of differing inbred strains. Unlike the viruses—which act only on animals of the sort from which they are procured or on closely related species—many of the carcinogens now in question are broadly effective, calling forth growths in a wide range of creatures from the frog to man. Yet what they call forth does not depend on them for its character but on the species of animal concerned and its breed, and even on the potentialities of the individual. Mice of differing inbred strains, when treated identically with a chemical carcinogen, will in some instances develop mammary tumors and in others lung adenomas, or liver tumors, bone tumors, lymphosarcomas or leukemia, according to the peculiarities of the strain to which each individual belongs (table 3). And the local neoplastic response when the carcinogen is brought into direct contact with a tissue (as for instance when tar is

TABLE 3—Induced Tumors as the Expression of Natural Liabilities

Animal	Natural Liability	Carcinogen	Authority
Mouse	Lung adenomas	Tar, benzpyrene, dibenzanthracene	Murphy and Sturm, Lynch, Furth, Andervont

applied to the skin) differs widely from animal to animal of the same breed, the experimenter having no control over where tumors will appear in the exposed region, or when, or how many of them there will be. He does not actually produce neoplasms at will in any of these instances but instead is like a fisher who casts a net for what he may draw in. He can be sure of the outcome only so far as he casts a wide and strong net—employs a powerful carcinogen that is to say, on a large expanse of tissue—and casts the net where he knows there are fish—in other words brings the agent to bear on tissues known to respond to it with tumors. Quite different is

²⁰ Personal observation.
²¹ Andervont, H. B., Grady, H. G., and Edwards, J. E. Induction of Hepatic Lesions, Hepatomas, Pulmonary Tumors and Hemangioendotheliomas in Mice with o-Aminoazotoluene, J. Nat. Cancer Inst. 3: 131 (Oct.) 1942.

the state of affairs with the viruses. The outcome with them does not depend on the potentialities of the tissues acted on, they bring along their own potentialities and selectiveness of action, with the result that they not only engender tumors at each spot where they are brought into contact with susceptible cells but determine the kinds that arise.

Since the generality of the carcinogens elicit neoplastic activities in which they take no further part it is scarcely surprising to find that their effect is disproportionate to the dose, tumors arising only when this is within a certain optimal range. The sarcomas appearing in response to an injection of benzpyrene into the connective tissue usually originate at some distance from where it exists in greatest concentration, and a strong solution of methyleholanthrene instead of producing tumors on the area of skin painted with it may do so only around the edge. The viruses in contrast cause neoplastic changes wherever they attain to cells of the right sort and the number of the latter infected and hence involved in tumor formation varies directly with the size of the inoculum.

In table 4 the relation of the viruses to the growths they engender is compared point for point with that of the other known carcinogens. It will be seen that these relations are fundamentally different. The generality of the carcinogens bring about tissue conditions out of which tumors may or may not arise for reasons still undetermined. They may fully be called provocative carcinogens. The viruses on the other hand both initiate tumors and determine their character and behavior. They are actuating carcinogens. This distinction deserves to be stressed because the viruses are often supposed to function in the same way as other carcinogens and hence are dismissed from attention as mere treacherous members of a large heterogeneous yet essentially single class of tumor-producing agents.

Certain instances there are in which viruses may function as provocative carcinogens instead of serving as the actuating causes of tumors. A papillomatous growth of man, condylomata acuminata, is due to a virus²² and when pent under a phimotic foreskin and aided by inflammation and maceration it sometimes burrows into the tissues perforating the foreskin and even penetrating to the urethra with result in fistulas. In these days of effective treatment such happenings are rare but they were carefully described and documented by many competent observers in the recent past.²³ Microscopic studies of the aggressive condylomas have shown that they invade and destroy normal structures as it they were malignant. Sometimes they cease these activities and revert to the ordinary state after circumcision is done showing that they were merely stimulated but in other cases they continue to invade and prove themselves to be truly cancerous by metastasizing. The cancers which are squamous cell carcinomas derive from the virus-infected papilloma cells by changes involving such slight morphologic alterations that surgical pathologists examining biopsy specimens, have time and again reported the growths to be invasive condylomas, learning their mistake only with the appearance of secondary nodules in the regional glands.

As yet nobody knows how far ordinary condylomas resemble true tumors, much less what happens when cancers derive from them. They are obviously infectious in origin, as the typical tumors are not, and furthermore they can seldom maintain themselves unless aided by local conditions such as are provided by bacterial or syphilitic infection with maceration. It may be that the virus responsible for them undergoes a variant

TABLE 4—Relationship of the Carcinogenic Agents to Tumors

The Neoplastic Viruses	The Generality of the Carcinogens
have similar general attributes	are of many diverse kind, are
are produced only from tumors	mostly extraneous in origin
act directly, making cells become tumor cells	act indirectly, by provoking chronic nonneoplastic tissue disturbance
increase as the tumors grow and are often recoverable from them	disappear as the tumors grow
are narrowly specific as concerns animals acted on and tumors produced	are largely non-specific as concerns animals acted on and tumors evoked
furnish the potentialities for tumor formation	are effective only if tumor potentialities are already present
then elicit determine the kinds of growth and link	evolve growths representative of preexisting potentialities
have effects proportionate to size of the inoculum	have effects of proportionate to the amount employed
They can initiate tumors	They provoke neoplastic change

change now and then becoming a cancer-producing virus, or possibly it works on the cells infected with it like an ordinary provocative carcinogen, with the result that they become malignant, owing to an alteration of some sort unknown or perhaps the attendant inflammation and maceration act in this way. There are large practical obstacles to settling the question.

A nearly similar sequence of events, presenting the same possibilities can be observed when virus-induced rabbit papillomas become cancerous, and it has the advantage for study that the growths can readily be experimented with. They have the immediate traits of true tumors, as already stated, and the carcinomas originating from them derive directly from the papilloma cells, elements easily discriminated from ordinary hyperplastic epidermis and owing their distinctive aspect to the action of the virus. After becoming malignant, the cells continue to exhibit some of the histologic features indicative of the influence of the latter, until as anaplasia ensues they lose the power to develop them. Often this does not happen the growths remaining malignant papillomas, even in metastases, and their cells showing peculiarities attributable to the virus until the animal dies. Furthermore, rabbits to which the cancers are successfully transplanted become strongly immune to the virus as the growths enlarge, showing that either it or some closely related antigen is present in the neoplastic tissue and increases in amount.²⁴ Inoculation of the skin of the cancerous animals now fails to result in papillomas, and their blood is no longer harmless to the virus when mixed therewith but neutralizes it rapidly and specifically. The antigen responsible for this acquired immunity was still abundant in the cancer even after it had been propagated in a succession of rabbits previously hyperimmunized to the papilloma virus.²⁵

although a similar procedure with other tumors of the extraneous viruses which sometimes gain access to them and ride along as passengers.²⁶

All this speaks for a continued participation of the papilloma virus or some near relative of it, in the activities of the cancer, and this interpretation of the findings gains further support from what happens when tar tumors are experimentally infected with the virus.²⁷ Most of the epidermal growths which appear on rabbit skin in response to tarring are benign papillomas, and they generally disappear after the applications are left off, if nothing further is done to them, but if the papilloma virus is injected into the blood stream of the host it frequently localizes in them and entirely changes the course of events. Some take on the character of virus papillomas, while others alter straightway to squamous cell carcinomas, and these may show the same histologic stigmas as the cancers of similar sort that derive from papillomas directly induced with the virus. Tar cancers already present are often spurred to sudden, great malignancy by the virus, and some of them show the alterations in morphology just mentioned as indicative of its influence. This disclosure that the virus can profoundly affect epidermal tumors of other origin makes the supposition well nigh untenable that it ceases to have any share in proceedings when the growths which it has itself caused become malignant. As bearing on the possibility that it undergoes variation to become a cancer-producing virus, the fact seems significant that the malignant change, though rare in cottontail rabbits, takes place with notable frequency in species to which the virus is foreign—swamp hares, jack rabbits, snowshoe hares and domestic rabbits especially—in all of which it readily produces papillomas on inoculation, for viruses are most likely to vary when propagated in hosts strange to them, as is well known. No one of many efforts, however, to induce variation of the papilloma virus by submitting it to the influence of methylcholanthrene or roentgen rays *in vitro* or *in vivo*, has thus far produced any qualitative alteration in its effects.

There would appear to be three possible ways to account for the observed phenomena when the papillomas become cancerous: (1) provocative carcinogenesis of the ordinary kind, the virus, or local conditions within the papillomas, acting on the infected cells in such wise that they change to cancer cells. On this supposition the cells swap horses while crossing the stream and emerge on its farther side as malignant, having wholly relinquished one neoplastic motivation for another; (2) provocative carcinogenesis, but with the virus persisting and influencing the cancers; and (3) variation of the virus, with result that it expresses itself in somewhat different terms, making the papilloma cells, which are already vigorously neoplastic, be cancer cells.

An obvious step toward learning the real state of affairs would be to get a virus of some sort from the

cancers, but all attempts at this have failed. For a while the failure seemed wholly attributable to the presence in the malignant tissue of antibodies extravasated from the blood, since they often accumulate in sufficient amount to render extracts of this tissue neutralizing for the papilloma virus when mixed there with. But recently a cancer derived from a virus papilloma has come to grow so fast, as a result of propagation in one favorable rabbit after another, that it furnishes considerable masses of tissue within a few days of implantation, before there has been time for the new host to form antibodies, and extracts of the tissue thus provided fail to yield virus, even when inoculated into skin previously rendered hyperplastic, a procedure which has disclosed the presence of the papilloma virus in many extracts that had seemed devoid of it when tested by ordinary methods. Nor has inoculation of the cancer extracts into epidermis behaving as if carcinomatous in response to scharlach R given any better result. If a variant of the papilloma virus is responsible for the cancers, either it must require conditions of a peculiar sort for its transmission, or else it has undergone such modification as to be incapable of infecting new cells, has become a dead-end virus, in short.

When the tumors elicited by the provocative carcinogens are scrutinized carefully, much that might be taken to imply a virus cause for them can be found. Such tumors can be easily produced in chickens by the injection into the connective tissue of tar, benzpyrene or methylcholanthrene, and in all their visible manifestations they are wholly like the various growths of fowls that are produced by viruses. No agents of the sort have been recovered from them, but this does not mean that such agents are absent. Indeed, as they enlarge the blood of the hosts comes to contain in many instances antibodies which will specifically neutralize one or another of the known chicken tumor viruses, as if this virus or some nearly related agent were contained in the neoplastic tissue.²⁸ The papillomas induced by tarring rabbit skin—indisputable neoplasms from which no cause has yet been got—resemble virus papillomas at all essential points²⁹ and like them may become cancerous secondarily, undergoing similar histologic changes then, with result in squamous cell carcinomas of the same sort. It is as if they were due to an agent somewhat less pathogenic but generally similar to the papilloma virus—which cannot be their cause, since the host animals fail to develop the specific virus-neutralizing antibody directed against it. Recently the tissue of the Brown-Pearce rabbit carcinoma, a transplantable squamous cell cancer long studied as a neoplasm of classic sort, has been found to contain an antigen which has much the same physical attributes as the papilloma virus, though distinct therefrom.³⁰ Like the agent present in the cancers derived from virus papillomas, this antigen induces the formation of an antibody peculiar to itself. Extracts of the neoplastic tissue fail, however, to produce tumors.

These findings indicate that the state of affairs encountered in the cancers derived from virus papillomas may be no unique instance but a representative

26 Living cells protect viruses with which they have become infected and hence the capacity of some of the latter to continue to do harm after the host has developed antibodies against them, and to persist for long periods. The success obtained in ridding tumors of passenger viruses by hyperimmunizing the host argues a less intimate association with the cell than exists under the ordinary circumstances of infection.

case. And there are other facts which should encourage persistent efforts to demonstrate viruses in neoplastic materials which have thus far yielded only negative results. Chicken tumors which have yielded viruses regularly for a long while may cease for considerable periods to yield any and then is unaccountably do so again.³¹ A transplantable fibrosarcoma of the towl, from which only inert extracts could be got during ten years of propagation has lately been proved due to a virus by utilizing differential centrifugation to remove a neutralizing antibody from the extracts prior to inoculation.³² Many rabbit papillomas induced with virus yet yielding extracts that proved innocuous on test—growths in which it was supposed to exist in 'masked' nonrecoverable form—have been shown to contain it in pathogenic state by introducing the extracts into skin rendered hypersusceptible to infection by previous preparation. Yet with all said one cannot attribute the general inability to get viruses from most tumors either to neutralizing antibodies or to technical shortcomings. There must be some deeper reason why this has not been possible.

On turning to consider again what the provocative carcinogens do, one finds uncertainties which are astonishing in view of the prolonged intensive work on this theme. Though the early pathologists realized that most cancers arise on the basis of chronic disturbance, no one has yet been able to determine what the local conditions are which bring on neoplastic change, tissue disorders which seem identical histologically are followed in some cases by tumors in others by none. It is plain that discovery must wait on methods whereby subtle cell changes can be brought to light. According to some investigators the chemical carcinogens, when painted on the skin act directly on the epidermis, which after a while responds with tumors whereas others hold that this response is secondary to a pathologic condition induced in the corium. Before growths arise epidermal hyperplasia usually takes place throughout the area affected by the carcinogens, but this is not always true and a good case has been made for the hypothesis that these agents act by bringing about conditions adverse to the cells,³³ with the result that they undergo conversion into tumor cells, presumably by mutant change. Whatever may be thought of this latter assumption—and the character of the recognized somatic mutations speaks wholly against it³⁴—many carcinogens are unquestionably injurious when applied in quantity. The effects of one of the most potent, benzpyrene, have been likened to those of an etching paste,³⁵ and it has even been used as such in Germany to destroy cancers of the face—though with grave danger of bringing on more cancers later, as need scarcely be pointed out. So pronounced is its influence to hamper tumor growth, and that of some other carcinogenic hydrocarbons, at least under certain conditions, that an active search has been begun for related substances which might be used against human cancer without risk of inducing additional tumors.³⁶

The accumulated observations of many workers have lately made plain that the provocative carcinogens in many instances elicit tumors of a sort that the animal is more or less likely to have spontaneously. Thus, for example benzpyrene, applied by a single route, may call forth mammary cancers, or liver or lung tumors, or lymphomas or bone tumors or some other type of neoplasm according as the individual or the breed tends to have such growths naturally (table 3), and the injection of estrogens brings on mammary tumors early and regularly in mice of strains which are prone to have them anyway and greatly increases the percentage incidence of such growths in breeds with lesser liabilities. How far this principle extends is still uncertain. Carcinogens often call forth growths which are rarely seen spontaneously in the kind of animal under test, but this may be only because the environmental influences playing on the organism have not been such as would evoke them. Skin tumors for example seldom arise under the natural conditions of mouse life, although they can be readily elicited by the application of the polycyclic hydrocarbons, but if mice are so placed that they cannot shield themselves from ultraviolet light of the wavelengths found in sunshine, skin tumors develop. And Spanish sunshine will actually call forth such tumors in rats, which almost never have them spontaneously. So well recognized now is the ability of the provocative carcinogens to bring lurking liabilities to consummation that when they produce a tumor of unusual sort under experimental conditions the first task of the investigator is to look into the provenance of the animal host with a view to learning whether its forebears, or others of its breed, may not have developed growths of precisely similar kind spontaneously. All this can only mean that the provocative carcinogens now utilized in the laboratory act through or on, the same mechanism as do the influences responsible for bringing on the tumors that arise under natural circumstances.

The known tumor-producing viruses do not depend on the intervention of the provocative carcinogens for their effectiveness, though possibly this may have been essential when they first caused growths. Mere trauma of the susceptible tissue with which they are brought into contact will suffice to ensure infection with them and its consequence, neoplastic proliferation. Yet nothing is more certain about the origin of most spontaneous tumors than that a disturbance such as the provocative carcinogens produce is an essential prerequisite to their occurrence. This being so, one must conclude that viruses requiring such slight tissue preparation as those now in hand cannot be the cause of tumors generally. And there are other obstacles to the virus theory. Each of the known neoplastic viruses is notably limited in scope, causing tumors in only a single species or in a few nearly related ones, as already mentioned, and with rare exceptions³⁷ each gives rise to growths of but a single sort, subject at most to minor modifications. Attempts to induce alteration of the viruses, with result in a variety of growths, have been fruitless save in an instance³⁷ in which the changes obtained in tumor type were too slight to lessen in any considerable degree the

magnitude of the theoretical problem presented. Must one invoke a whole world of viruses to explain the diversity of tumors? And how account on the virus supposition for those growths which, occurring at wide intervals of time or space, have yet identical peculiarities? Certainly the passing on of a pathogenic agent from one individual to another cannot be responsible in their case. And the evidence is all against the direct transmission of an actuating cause for even the commonest of mammalian tumors. It even seems unlikely that the virus causing the sarcoma known as chicken tumor I, an agent so pathogenic as to produce growths within a few days after experimental inoculation, is ever directly transferred under natural conditions. For not only do no new sarcomas arise when normal fowls are crowded with those carrying growths induced with the virus, but the latter undergoes swift inactivation when separated from the sarcoma cells unless special means are taken to preserve it. The fact that the papillomas of wild cottontail rabbits are so frequent in some localities as to suggest an infectious process renders them exceptional among the neoplasms.

The difficulties of supposing that viruses cause the generality of tumors have forced those interested in the concept to make several assumptions.³⁸ To account for the worldwide distribution of tumors and for the occurrence of growths of peculiar type at widely separate intervals of space or time it has been necessary to suppose that the body carries resident viruses just as it does resident bacteria indigenous viruses as they have been termed, which ordinarily are harmless but now and again become so changed in response to intercurrent conditions as to work on the cells with which they are associated, with the result that these become tumor cells. Such viruses might reach young creatures in early life by transfer from parent to offspring either in utero—as lymphocytic choriomeningitis does in mice³⁹—with result in an infection that is often inapparent—or after birth like the symbiotic bacteria. They would give no sign of their presence in most instances and would in due course be passed on to the young. But if a provocative carcinogen happened to work on the cells with which such a virus was associated thus altering its milieu, it might undergo variation and, taking a hand in cell affairs for the first time, give rise to a tumor. The new pathogenic variant would not be transmitted to other animals under natural circumstances, for reasons as yet obscure, but would be a dead-end virus not concerned in the production of other neoplasms, though the harmless source virus liable to the same or other variations would be passed on.

Recent discoveries have provided an instance in real life which embodies this conception almost point for point. Its history is as follows:

Some years ago geneticists studying strains of mice with a pronounced tendency to mammary cancer in old females found by cross breeding with strains almost free from such cancer that the tendency to the disease came from the mother's side.⁴⁰ This led to tests in which newborn female mice of "high cancer" strains

were suckled by "low cancer" foster mothers. It turned out that in this way the young had been rescued in nearly all instances from mammary cancer, living out their lives free from it, and further work showed they had been prevented from acquiring something which ordinarily comes to the young in the milk of mothers of cancerous strain,⁴¹ the "milk influence" or "mammary tumor factor," as it has been called. Yet these mothers did not have cancer at the time when they passed on the "influence" nor did the young that they themselves suckled develop the disease forthwith but only long after growing up. Even from the tissue of the mammary cancers nothing could be got that would cause tumors directly though it yielded the "milk influence" on extraction as did also the ordinary breast tissue for that matter. The young of low cancer strain acquiring this "influence" passed it on in due course to their offspring and these in turn to theirs, litter after litter and generation after generation, plain evidence that it underwent increase within the individual body. It not only failed to cause cancer on direct inoculation but it was ineffective unless the mammary glands developed, and the action of the estrogenic hormones was necessary to this. The occurrence of the tumors could be greatly hastened and their incidence increased by administering the hormones in excess. The powers of the estrogens in such respect, as provocative carcinogens had been noted some years before the "milk influence" was discovered.⁴²

Chemical and physical studies of the "influence" have shown it to have a large molecular weight and to be in all probability a nucleoprotein. It passes through bacteria-tight filters, resists drying and has other physical traits such as viruses exhibit. Presumably it enters the blood from the highly permeable gut of the suckling and, reaching the mammary tissue, finds lodgment there. When it is fed experimentally to mice having but a slight natural liability to mammary cancer the incidence of the disease may be increased somewhat but animals of some breeds have shown themselves to be by inheritance unfavorable as hosts for it. Not only must the local state of the tissues (as determined by the estrogenic hormones) be right if it is to give rise to cancer but the individual animal must be of susceptible sort. The conditioning is not unlike that which obtains with many infective agents.

It will be seen that all this corresponds closely with what would have to be true of viruses if they were the actuating causes of tumors generally. As already stated they would have to be widely distributed and pass from one animal to another, presumably early in life, to reside in the tissue and cause no tumors save on special occasion. That is what the "milk influence" does. But if a provocative agent, a carcinogen, so called, happened to work on the cells with which an indigenous virus was associated, then, according to supposition, it might become pathogenic and undergo alteration to a tumor producing virus. Again the facts about the "milk influence" accord with theory. For not only has it been found that the estrogens, when provided in excess, enhance the natural liabilities to "milk influence"

tumors⁴³ by producing tissue disorder is the way with the provocative carcinogens but one of the potent carcinogenic hydrocarbons methylcholanthrene a substance devoid of estrogenic effect makes them appear very soon and in great number when it is applied to mice of a strain in which the "milk influence" exists.⁴⁴ The failure to get viruses from some tumors in which there is good reason to believe them present has led to the assumption that they are dead end viruses incapable of further transmission and that only the harmless virus from which they derive is passed on. The harmless "milk influence" is passed on, yet from the mammary cancers due to its presence in the tissues nothing that will produce such growths has thus far been recovered.

The breast tissue of animals acquiring the "milk influence" differs from the ordinary as time goes on scattered adenomatous nodules forming from one or more of which carcinomas take origin.⁴⁵ These latter are the outcome of a two stage process, of a primary neoplastic change which results in benign growth and a superimposed, second one which finds expression in malignancy. So too with many other cancers for example the carcinomas arising from the cutaneous papillomas of unknown cause which appear in response to tar or other carcinogenic hydrocarbons, and those originating from virus-induced papillomas. Once the benign neoplastic change has taken place which results in the papillomas malignant tumors may develop secondarily without further tarring yet this increases pronouncedly the likelihood of cancers and hastens their appearance while as already mentioned methylcholanthrene has similar effects in the case of "milk influence" carcinomas. All this being so it has seemed worth while to inquire whether the occurrence of malignant change in benign tumors of virus origin the rabbit papillomas so often mentioned may not be furthered by the application of provocative carcinogens. This has turned out to be the case.⁴⁶ Both tar and methylcholanthrene are notably effective causing multiple squamous cell carcinomas to arise from virus papillomas with unprecedented rapidity. Ulcerating metastasizing cancers have appeared in response to methylcholanthrene as early as seventy-one days after virus inoculation that is to say after sixty-four days of papillomatous growth. Control tests have shown that no ordinary stimulants of cell proliferation bring on the malignant change so soon or with anything like the same frequency.

Whatever the character of the "milk influence" its discovery suggests an explanation for the differing neoplastic liabilities of inbred animals. It has been difficult to understand why a provocative carcinogen should call forth mammary tumors in mice of one strain and lung or liver tumors, or lymphosarcomas or bone tumors respectively in others, and why individuals of identical strain and so alike genetically that the transplantation of normal tissues readily succeeds in them should in some instances develop tumors infrequently and late

in response to a carcinogen while others acquire many growths soon. No such divergences in pathologic response were to have been expected of cells which under normal circumstances perform identical functions and are wholly alike in aspect. But if neoplastic potentialities come to the cells from without, instead of being inherent all at once becomes clear.

The mammary cancers due to the "milk influence" exhibit considerable variety but as yet it is not certain how the agents of the sort are responsible for tumors in general. The liability to leukemia exhibited by some strains of mice is transferred by way of the milk but the tendency to lung and liver tumors seems not to be passed on thus.⁴⁷ Recent indications that the influence responsible for mammary cancer may in some part reach the young during uterine life⁴⁸ open a vista of possibilities in relation to other tumors.

Here this discussion of the nearer causes of cancer must come to a close. Those carcinogens which merely provoke the disease are crucial to it nevertheless since without them it would not occur. Many are so powerful the roentgen rays and certain synthetic hydrocarbons for example, that they bring tumors into being which under ordinary circumstances would never occur. They crash the gates of ordinary insusceptibility. Not a few agents to which man unwittingly exposes himself under the circumstances of ordinary life are scarcely less effective. A list of the human tumors which have been traced to the action of provocative carcinogens is in no small degree a sociological document reflecting as it does the ways of life, vocations, avocations, habits and environmental stresses of peoples and individuals. The occurrence of betel nut cancer in Siam, of kangri cancer in Kashmir, of mule spinners' cancer in England and of osteosarcoma due to radium emanation in the United States demonstrates as clearly as the experimental findings in mice that every animal body possesses a myriad of potentialities for tumor formation and that only by good fortune do most human beings slip through life without the realization of a single one of them.

More and more with each recent year investigators have come to realize that the human tumors which seem spontaneous whose method of origin is still obscure, must actually be brought on by provocative carcinogens of one sort or another. Only lately they have perceived that hormones when functioning in excess may render tissues so abnormal as to start tumors off, and now they are asking whether disordered metabolic processes may not lead to the manufacture of endogenous carcinogens. From all sides evidence is coming in to justify the axiom that every spontaneous tumor is an induced tumor. It is an axiom which should spur clinician and laboratory worker alike to be forehanded with cancer.

The episodic discovery that viruses are the certain cause of some growths and probably are responsible for more seems extraneous and discordant when first considered in relation to the ordered progress of thought and endeavor which has revealed, little by little the decisive share of the provocative carcinogens in the origin of tumors. But in reality it fits into the pattern of things. For workers at the cancer problem have begun to see that they must look beyond the provocative carcinogens for the actuating causes of tumors, the unknowns which make these what they are.

10 After twenty minutes the rate is slowed to 15 drops per minute. This rate of flow is usually sufficient to maintain even anesthesia. In a few cases a slightly higher rate than 15 drops per minute was found necessary. The level of anesthesia must be carefully watched,

and if the cutaneous anesthesia goes above the umbilicus the procaine hydrochloride is temporarily shut off.

RESULTS

We have used the revised method for labor and delivery in 61 cases. These cases, combined with the 39 cases from our previous series, make a total of 100 cases in which continuous drip caudal anesthesia was given in obstetrics. The results were good except in a few instances. The one serious complication, the spinal injection of procaine hydrochloride, occurred before we had instituted the saline test. In the great majority labor was painless and delivery ac-

complished without any supplementary anesthesia. A few patients continued to have some discomfort but even they had considerable relief. The length of labor is apparently shortened by continuous caudal anesthesia. The average primipara delivered four hours after the caudal anesthesia was begun and the multipara in two hours. It is to be noted that caudal anesthesia was not given as soon as labor began but, like ordinary analgesia, only after labor was well initiated and when the patient objected to her pains.

Caudal anesthesia does not interfere with a spontaneous delivery. When the time comes, the patient is instructed to bear down properly. It is the policy of this clinic to do a routine episiotomy and low forceps on the primiparous patients, but on several occasions when we desired to demonstrate a spontaneous delivery under caudal anesthesia it was easily accomplished with the cooperation of the patient's voluntary expulsive efforts.

There were four fetal deaths in this series of one hundred deliveries. One fetus was macerated, fetal heart sounds were not present on admission. The second showed congenital absence of the left diaphragm and lung at autopsy. The third lived thirty-six hours, and pneumonia neonatorum was found at autopsy. The fourth was stillborn, and no demonstrable cause of death was found, although two tight loops of cord were present around the neck at delivery. The other 96 babies cried spontaneously, many even before delivery could be completed.

Supplementary anesthesia was given to 7 patients. Three of them did not get sufficient perineal anesthesia, and we electively gave inhalation anesthesia to the other 4 (1 internal podalic version, 1 high midforceps and 2 Kielland forceps with rotation from the transverse). The last 3 cases occurred early in our use of caudal anesthesia, and since that time we have completed delivery in several similar cases without the addition of general anesthesia. The elimination of inhalation anesthesia was very helpful in cases in which labor was complicated by a pulmonary or cardiac condition.

COMPLICATIONS

The third stage of labor appeared to be completed with less than average bleeding. There were no instances of extreme hemorrhage, and in most cases the bleeding was minimal. There were 2 cases of retained placenta, 1 required manual removal under general anesthesia.

We have had about 95 per cent success in inserting the needle into the caudal canal. In a few cases, either because of anatomic variations or because of excessively thick tissues, we have been unable to do so and consequently were forced to resort to some other form of analgesia.

The likelihood of the needle breaking off in the back is becoming less frequent. At first this was not an uncommon occurrence, but as the quality of the needles improved this mishap has become rare. In our last 75 cases only one needle broke and since then new and

Fig. 5—Position of patient under the anesthesia. A flask containing isotonic solution of sodium chloride. B flask containing procaine hydrochloride 1 per cent.

Fig. 6—Needle lost in caudal canal.

better needles have been developed, the use of which is not included in this article. It is a simple matter to remove the needle when the break occurs in the subcutaneous tissue. However, if it is in the caudal canal it is more serious. This happened in 1 of our cases, and despite two hours of exploration by an experienced surgeon the needle was never recovered (fig 6).

The most serious complication is accidental injection into the subarachnoid space. This occurred in 1 of our cases before the saline test was introduced. This case has previously been reported in detail.³ The patient went into profound peripheral vascular collapse and probably would have died but for prompt therapy by a competent anesthetist. The possibility of dural penetration must always be anticipated and one should be prepared to resort to combat this catastrophe.

Fig. 7—Number of drops per minute immediately after administration of saline solution was started in the caudal space (69 cases)

Careful observation of the patient throughout the period of caudal anesthesia is essential. The level of cutaneous anesthesia should be kept at the level of the umbilicus. The level of the anesthesia depends on two factors—the rapidity of administration and the volume of solution used. We have found that when either or both of these factors are ignored the anesthesia may go to so high a level that serious cardiovascular complications may be encountered and an alarming fall in blood pressure and other symptoms of peripheral vascular collapse may occur. If these symptoms appear epinephrine sulfate should be given immediately and the anesthetic temporarily clamped off. The best treatment for this complication is prophylactic; the anesthesia must be constantly supervised by a competent person and the height of cutaneous anesthesia tested at regular intervals.

Sensitivity to procaine hydrochloride has been a minor complication. A few patients have complained of drowsiness, headache or nausea and an occasional patient has vomited, but the majority have not exhibited any untoward effects.

Postpartum complications were negligible. There were no cases of epidural abscess. Low back pain was a frequent complaint until a routine postpartum prophylactic injection of morphine ($\frac{1}{2}$ grain [0.01 Gm]) every four hours for three doses was given. This has virtually eliminated the difficulty. We kept some patients in the lateral position throughout labor, as advocated by Edwards and Hingson, while using the continuous drip caudal but it proved less satisfactory than with the patient flat on her back. Lying on one side tended to produce unilateral anesthesia on the dependent side.

APPLICATION TO OBSTETRIC SURGERY

The continuous drip technic was also applied to obstetric surgical procedures. Five cesarean sections, two abdominal hysterotomies, two Pomeroy sterilizations with appendectomy and two curettages were done.

In order to apply the method to abdominal operations, a few revisions in technic were required. The anesthesia should be started forty-five minutes prior

to the incision and 1 per cent procaine hydrochloride is allowed to drip in at the rate of 30 drops a minute for thirty minutes. The inflow is then reduced to 20 drops a minute and the solution allowed to run at that rate throughout the operation. No inhalation anesthesia or auxiliary analgesics were needed. The patients experienced no pain and their postoperative conditions were excellent. All the babies delivered by cesarean section cried spontaneously.

There were no serious complications. Two patients who underwent cesarean section had a pronounced fall in blood pressure but responded promptly to epinephrine sulfate $\frac{1}{2}$ grain (0.05 Gm). We now are giving epinephrine sulfate routinely in all cases of abdominal surgery preoperatively when continuous caudal anesthesia is to be used.

COMMENT

We have done one hundred deliveries and eleven obstetric surgical procedures under continuous drip caudal anesthesia and the preliminary saline test in the last 69 cases. The differences between the caudal and the spinal rate of inflow were so clearly defined that we did not deem it necessary to continue to subject every woman in labor to the added annoyance of a spinal tap. Therefore after the first 15 cases we no longer took the spinal rate but confined the test to an immediate (fig 7) and then after three minutes a second count (fig 8) of the flow into the caudal canal.

A 150 drop per minute rate of flow after three minutes was used as the upper limit of safety and for that reason the anesthetic was withheld from 2 patients who had a rate of 210 drops per minute even though we could not aspirate spinal fluid from the needle (fig 8).

In doing the experimental work we used the fourth lumbar interspace for our spinal taps. In order to prove that the site of the puncture is unimportant we were successful in 2 cases in intentionally piercing the dura through the caudal canal with a $3\frac{1}{2}$ inch needle.

Fig. 8—Number of drops per minute after saline solution had dripped for three minutes into the caudal space (69 cases)

After obtaining spinal fluid as confirmation we observed a saline rate of over 210 drops per minute.

The decidedly slower caudal rate probably depends on the fact that the caudal canal anatomically is almost a potential space and therefore offers resistance to fluid introduced by gravity. This is further borne out by the fact that the number of drops per minute that will drip into the caudal canal becomes progressively lessened as the canal is increasingly distended.

One per cent procaine hydrochloride was found to be completely satisfactory. It is less expensive than

metycaine, and no serious toxic effects have been encountered from its use. Since we give the anesthetic continuously we find its shorter lasting period of anesthesia to be advantageous. It was given as long as eighteen hours without complication. The average total dose was 200 cc. The largest dose was 850 cc. Relief from pain begins in ten to fifteen minutes, and complete anesthesia is obtained soon thereafter.

In the previously reported series, caudal anesthesia was begun very early. It was started as soon as it was certain that the patient was in labor. We now believe that it is wiser to withhold the anesthetic until pains are severe enough to make the patient uncomfortable. This is done for three reasons: 1. Labor seems to be more rapid. 2. It reduces the total procaine hydrochloride required. 3. The patient appreciates the anesthesia more because she can compare her comfort before and after its use.

SUMMARY

The continuous drip technic for the administration of caudal anesthesia for labor and delivery which we have presented may be modified also for surgery. It appears safer than the method now in general use, because it represents a truly continuous technic and large doses are thus avoided at any one time.

Criteria have been established to determine whether the needle is extradural or intradural. The spinal canal has been entered inadvertently if (a) spinal fluid can be aspirated, (b) the immediate flow of saline solution from a continuous drip reservoir exceeds 210 drops per minute and (c) there is no appreciable diminution in the rate of flow after three minutes.

The needle is in the subcutaneous tissue if (a) pressure proximal to the needle stops the free flow of saline solution, (b) a bulge develops over the sacrum where the fluid has extravasated into the tissue.

The needle is in the caudal canal if (a) no spinal fluid can be aspirated, (b) pressure over the sacrum does not stop the free flow of saline solution and (c) saline solution from a continuous drip reservoir flows in at a rate less than 150 drops per minute after three minutes.

Continuous caudal anesthesia has been a very satisfactory technic in our hands. Certain highly dangerous complications are possible and therefore it should be given only in well equipped hospitals by persons experienced in the technic.

Monument Street and Rutland Avenue

Estimate of Number of Patients Having Gout—Hench has affirmed that patients with gouty arthritis constitute at least 5 per cent of all patients seen at the Mayo Clinic suffering from the several diseases of the joints. A similar percentage has been observed in other clinics. If this value is valid throughout the United States, there may be at least a third of a million people suffering from gout among 7 million sufferers from chronic rheumatism. It is safe to estimate that only a portion of this number is diagnosed as gout and treated for same. One reason for the discrepancy between probable incidence and clinical recognition is the common failure among physicians of waiting until advanced tophaceous changes in the joints have appeared before suspecting gouty arthritis. Another reason is the lack of unanimity regarding criteria for a diagnosis.—Talbot, John H. *Gout*, New York, Oxford University Press, 1943.

PERIPHERAL NEURITIS AS A COMPLICATION OF PERNICIOUS ANEMIA

AND COMBINED SYSTEM DISEASE

JOHN B. DYNES, M.D.

AND

JOHN W. NORCROSS, M.D.

BOSTON

The literature concerning pernicious anemia and its associated neurologic complications, both clinical and pathologic, is voluminous. We should like to call attention to certain clinical aspects which, although not entirely neglected in previous reports, have not, we feel, been emphasized sufficiently. The specialist is quite familiar with the various aspects of this problem and with the variability of the neurologic complications of pernicious anemia. This brief review is directed primarily, therefore, to the general practitioner who first sees and examines these patients and starts them on a course of treatment.

When one considers the neurologic disorders which may precede,¹ accompany or follow the onset of pernicious anemia, one invariably thinks of subacute combined system disease. There can be little question that sclerosis and degeneration within the posterior and lateral columns of the spinal cord² have been the most frequently observed pathologic findings. The most common clinical finding³ related to the nervous system in patients with pernicious anemia is paresthesia and dyesthesia of the feet and hands, and frequent impairment of vibratory and position sense particularly in the feet. It is generally believed that the clinical findings are to be explained on the basis of the degree and location of the neuropathologic findings. The actual cause of these neuropathologic changes is still a problem, since there are a number of clinical conditions which may give rise to similar findings in the spinal cord. In more recent years vitamin deficiency has been thought to play a part in producing these changes, both in laboratory animals and in patients, but it would seem in most cases that there is a combination of factors. Although vitamin deficiency may be important, it usually does not operate alone to produce these pathologic changes.

Some writers⁴ call attention to the fact that the degree of sclerosis in the posterior and lateral columns of the spinal cord does not always parallel the severity of the clinical symptoms and, conversely, that the patient may have severe subjective changes and yet have little to explain these symptoms on pathologic examination of the spinal cord.

This has led other investigators⁵ to suspect that the peripheral nerve may be the source of certain clinical

symptoms and signs. Early work on this point⁶ tended to be inadequate and lacked confirmation. In more recent years neuropathologic investigation⁷ has confirmed the presence of peripheral nerve disease in many patients with pernicious anemia who have neurologic complications.

In medical teaching of the pernicious anemia syndrome it is not uncommon to stress spinal cord disease and the accompanying neurologic signs while either entirely neglecting or at least failing to emphasize the fact that neurologic examination reveals unusually variable signs. This variability tends to make diagnosis more difficult for one who has a limited experience with these disorders. The neurologic signs may not conform with the common conception of what the typical findings should be in cases of pernicious anemia. As a rule one expects to find increased tendon reflexes in the lower extremities with bilateral extensor response (Babinski), diminution or absence of vibratory sense in the feet and lower legs, impaired position sense of the toes, ataxic gait, positive Romberg's sign and absence of abdominal reflexes. One soon discovers that many patients have absent reflexes at the ankle and perhaps a complete loss of tendon reflexes in the lower extremities. In some patients the paradoxical findings of a positive Babinski sign associated with absent tendon reflexes may be demonstrated. Russell Batten and Collier⁸ in 1900 called attention to this particular combination of signs and suggested that they should make the examiner consider subacute combined system disease. Absent tendon reflexes frequently have been explained on the basis of involvement of the posterior columns of the cord and the interruption of the reflex arc in very much the same manner as in tabes dorsalis. In some cases this explanation may be quite valid, but it does not explain why certain patients with definite clinical evidence of posterior column disease continue to show increased reflexes, though one may concede the pyramidal tracts to be irritated.

There is another explanation which either in whole or in part may account for the absence of reflexes in a patient who otherwise has combined system disease. The latter explanation is concerned with the peripheral nerve and is one which we feel is usually given too little consideration.

Generally the clinical diagnosis of peripheral neuritis is made on the basis of peripheral nerve pain, dysesthesia or paresthesia, tenderness on pressure over the nerve trunks or muscles usually with evidence of some muscle weakness as the disorder progresses, and a loss or diminution of tendon reflexes starting distally. There is also a tendency to a distal superficial hypesthesia to pain and touch. In severe cases of peripheral neuritis one has little or no difficulty in making a diagnosis. However if the disorder is one of a milder character or one which has been present sometime in the past, the acute signs and symptoms may have diminished greatly and one therefore has fewer diagnostic criteria on which to render an opinion.

Some years ago, certain investigators⁹ believed that the neurologic complications of pernicious anemia did not respond to liver treatment, while others¹⁰ held a more optimistic point of view. At the present time, all of those who actively are studying the problem find much improvement on adequate parenteral liver treatment. Strauss, Solomon and Fox¹¹ have particularly emphasized the necessity of adequate treatment, and under such conditions these patients may be greatly improved clinically, both subjectively and objectively and the disease process arrested. Davison's¹² recent neuropathologic investigation would seem further to confirm this view. The neuritic manifestations tend to respond to treatment before the abnormalities of combined system disease.

Patients suffering from pernicious anemia frequently lose their appetite, lose weight and develop a glossitis or stomatitis. An intercurrent infection may contribute to the development of neuritic symptoms. The relationship of vitamin B deficiency is strongly suggested but

Probable age of onset of symptoms in cases of pernicious anemia

has never been unequivocally demonstrated, and, in general, patients do not respond to vitamin therapy alone.

We have reviewed 92 cases of pernicious anemia, all of which were seen and examined by one or both of us. In a survey of this case material we have used the criteria stated in a previous paragraph in making the diagnosis of peripheral neuritis. Of the 92 patients having definite laboratory, clinical and therapeutic evidence of pernicious anemia 21, or approximately 23 per cent, had unmistakable peripheral neuritis in combination with combined system disease. An additional 22

patients or about 24 per cent, had the clinical signs of combined system disease without peripheral neuritis, while the remaining 49 patients, or 53 per cent of the series showed evidence of pernicious anemia without clearcut neurologic signs.

An attempt was made in the analysis of our cases to discover some factor underlying the development of

Review of Cases

	Neuritic	Nonneuritic
Number of cases	21	71
Sex: Male	0	21
Female	15	47
Average age on entry	36.7 yr (10.72-57.1)	40.3 yr (15.70-57)
Average duration of symptoms on entry	2.3 yr (5 mo-16 yr)	2.8 yr (7 mo-23 yr)
Average weight loss	16.1 lb	16.2 lb
Cases presenting gastrointestinal complaints	11 (52%)	15 (21%)

the neuritis. The age of onset showed no significant difference in the three groups of cases, nor did the average duration of symptoms or the average weight loss throw any light on the problem. However, it was found that about 50 per cent of the neuritic group had definite gastrointestinal symptoms on entry as compared with 21 per cent of the cases not showing neuritic manifestations as shown in the accompanying table and chart.

The treatment of patients with neurologic complications must not be controlled solely by studies of the blood. When the red blood cell count and hemoglobin have reached normal levels and the macrocytosis has entirely disappeared the neurologic symptoms have sometimes not even started to respond. This is to be expected when one considers the varying level of anemia that may be present when neurologic manifestations become evident. Therefore in our opinion, the one criterion of adequate treatment is the improvement of these neurologic changes both subjective and objective. We believe that, if no response occurs, sufficient parenteral liver extract has not been administered. It is thought desirable to eliminate foci of infection and to improve the patient's general health if liver and vitamin therapy are to be successful in all cases.

When the highly concentrated liver extracts were first made available many including ourselves suspected that the less concentrated extracts would prove more efficacious in treating the neurologic manifestations of pernicious anemia. This has not been the case, as proved by a year's trial with a highly concentrated extract containing 15 U S P units per cubic centimeter. During this time no patient previously controlled on less concentrated extract showed progress of his disease. Each new patient who was given the highly concentrated liver extract (15 U S P units per cubic centimeter) demonstrated the expected degree of therapeutic response. This has also been the experience of others.¹³ Because of the higher cost of the more concentrated liver extract, we routinely use the crude type.

It is our practice to treat patients demonstrating severe neurologic complications with 20 U S P units (33 U S P units per cubic centimeter) of liver extract intramuscularly daily for several weeks and then to continue this dose every second day for several months. Thereafter 20 U S P units should be administered

at least twice a week until the neurologic manifestations have improved definitely or cleared entirely. The amount of liver extract needed varies considerably with the patient. The speed with which the red blood cell count and hemoglobin attain normal levels and the red cells lose all evidence of macrocytosis is of secondary importance to the continued neurologic improvement. Large doses of a potent vitamin B complex preparation are always given as supplemental therapy.

The response of patients suffering from peripheral neuritis in addition to combined system disease has progressed more rapidly and has been on the whole more complete than has occurred in patients with combined system disease alone. Of our 21 cases demonstrating definite evidence of both neurologic complications, 16 have responded well with pronounced regression of symptoms and unmistakable reversion of signs toward the normal. One case of seven years' duration responded poorly while the response in 4 cases is unknown, 2 of these are too recent to evaluate, 1 patient is dead, and 1 could not be followed.

SUMMARY

1. In a series of 92 cases of pernicious anemia, 21, or about 23 per cent, demonstrated clearcut evidence of peripheral neuritis and combined system disease.
2. An additional 24 per cent showed combined system disease without peripheral neuritis and 53 per cent pernicious anemia uncomplicated by neurologic signs or symptoms.

PROPHYLACTIC USE OF SULFA GUANIDINE

LIEUT JAMES CLIFFORD SCOTT (MC), USNR

On Oct. 24, 1941 a case of diarrhea with fever developed at the Devereux Gateway School, which is one unit of the schools operated by the Devereux Foundation, Devon, Pa.¹ This unit is operated for the care and training of children from 3 to 8 years of age, all of whom are mentally defective to some extent. On the following day the second child became ill in the same manner, and from then on, in spite of the usual treatment used for the control of diarrhea in childhood, we were faced with a rapidly developing epidemic in the building with all cases running virtually the same course of illness.

Cultures of the stools of all children were made, and the Bryn Mawr Hospital Laboratory isolated from 4 active cases organisms identified as the Sonne type of dysentery bacillus. Details of the symptoms together with the laboratory findings, gave me full confidence that we were dealing with a perfectly clear cut epidemic of bacillary dysentery.

SYMPTOMS

Since the first diagnosis was made clinically and since the final diagnosis in our cases depended partially on clinical symptoms and signs, I believe that, in order to establish the fact of an epidemic of actual bacillary dysentery, a description of the signs and symptoms is necessary.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

1. Lieutenant Scott is medical director on leave of absence for the duration of active duty of the Devereux Foundation, Devon, Pa.

A Nine Year Study of Maintenance Requirements, with a Note on the Efficacy of Purified Liver Extracts in the Control of Neural Lesions, New England J. Med. 226: 1013-1015 (June 25) 1942.

All the children described as suffering with the illness presented remarkably similar symptoms and chronology of illness except as they differed with the day on which they were given treatment with sulfaguanidine. Every attack began suddenly with apathy, loss of appetite, fever, hyperperistalsis and within a period of an hour or more acute diarrhea with innumerable stools both continent and incontinent. All the children during the acute period of the disease before institution of treatment appeared more ill than the degree of fever (from 100.5 to 104.0 F rectally) would usually indicate in children of this age. The stools were all liquid and foul and contained leukocytic exudate combined with food particles and gross blood in most cases. Most of the children had some degree of vomiting during the first thirty-six hours. In all cases the usual methods of treatment for diarrhea in children were instituted as soon as symptoms appeared and as these took effect to relieve the general condition of the child the appearance of toxemia would improve to some extent but none of the children fully recovered until they received either the therapeutic or the prophylactic dose of sulfaguanidine. However regardless of the time elapsed between the onset of illness and the institution of the sulfaguanidine therapy, every child without exception showed decided relief of all symptoms in from twelve to twenty-four hours after starting this therapy.

The therapeutic dosage used was designed as closely as possible to conform to the recommendations of Marshall and his associates,³ namely 10 mg per kilogram of body weight for the first dose followed by 5 mg per kilogram every four hours day and night thereafter.

Since the effectiveness of the drug used therapeutically in this disease seems to me to have been firmly established by previous reports of other authors I feel that no further discussion of results of treatment is here indicated. This paper is principally concerned with the prophylactic use of the drug.

A careful review of the literature at the time of writing has failed to disclose a description of an epidemic of this sort being controlled by the prophylactic use of sulfaguanidine and since this drug was used prophylactically in this epidemic with what appears to be perfect success, I feel that some details of the epidemic and our results with sulfaguanidine used in this manner should be published since the disease may be the source of a great deal of morbidity and loss of time especially in wartime.

The use of the drug therapeutically seems to require little more to be said in its favor except that in reviewing the literature I came across a curious fact which is not specifically mentioned in any of the papers. This concerns the toxicity of sulfaguanidine. In every report of toxic reactions that I was able to find the drug had been used in conditions in which there was a known break in the continuity of the epithelial wall of the intestinal tract or in conditions (such as typhoid) in which although the existence of such a break was not definitely known, such a break would naturally be expected to exist. This fact would seem partially to explain the disagreement between many physicians who have been able to use the drug extensively without a sign

of toxic reaction and a number of authors⁴ who warn specifically that use of the drug has been dangerous in their experience. I believe that, if given to patients who have no intestinal ulcers or other breaks in the mucosa sulfaguanidine is the drug of choice in bacillary dysentery.

The work of Marshall and his co-workers³ in January 1941 has become the classic work on the drug. They described its physical qualities and the first extensive use in animals and man. Their finding that it absorbed (as it is in the rabbit) the drug is very toxic fits in with later findings clinically that when absorbed in man as it definitely is in the presence of ulceration of the bowel the drug is dangerously toxic. In other cases the drug compares favorably with sulfaiazine in its absence of toxic reactions. In handling a very large series of cases in an epidemic of bacillary dysentery in the New East where only the sickest patients were treated with sulfaguanidine Fairley and Boyd⁵ reported that in 371 of the most severe cases toxic reactions were very mild and consisted only of headache associated with malaise and an occasional transient erythematous rash or a mild papular eruption.

A publication by Bloomfield and Lew⁶ indicated that the drug was effective in eliminating a troublesome epidemic of ulcerative colitis among their laboratory rats and no doubt this information had some influence in leading to its trial in ulcerative colitis in man. Such trials have been very disappointing and have led in almost all published reports to warnings concerning its toxicity.⁷ In the treatment of typhoid the drug has been most disappointing and in some cases harmful.⁸ However Levi and Willen⁹ found the drug effective in ridding a typhoid carrier of the infection when all other measures including appendectomy and cholecystectomy, had failed. It would be natural not to expect ulceration in such a case.

Every published report of the use of the drug therapeutically in bacillary dysentery is consistent in reporting good results with almost negligible toxic reactions.¹⁰ For this reason I feel that I should not burden the reader with a discussion of the therapeutic response in my epidemic except to say that in every case improvement of the child in every way in the first eighteen

hours was dramatic, that cure was effected in all cases within a very short time and that no relapses occurred. The dosage and techniques used followed as closely as possible those recommended by Marshall and his co-workers.¹ No toxic reactions of any sort were observed in any of the 20 patients treated with the drug, or in the other children, nurses, cooks, waitresses, attendants and teachers who voluntarily took the sulfaguanidine in small doses as a prophylactic measure.

EPIDEMIOLOGY AND PROPHYLAXIS

Therapeutic use of sulfaguanidine had been started on the ninth day of the epidemic, but in spite of this fact the number of our children ill in bed rose steadily, because although those treated were rapidly recovering, new cases were developing faster than recoveries were being made. This is illustrated in the accompanying chart. An interesting fact about our epidemic was that for the first ten days all patients were living on the second floor. The fact that all the children were fed by the same attendants and nurses and that the food

Course of epidemic of bacillary dysentery showing sudden arrest after prophylactic use of sulfaguanidine

was all prepared in the same kitchen by the same cooks indicates that the original infection developed in a child on the second floor. Although unable to prove his responsibility, we suspected 1 boy who had come to us six weeks before with a history of recurrent unexplained diarrhea at intervals throughout the preceding three months. He was the son of a physician and had been well studied. This was one of the children in whom the laboratory was able to demonstrate the dysentery bacillus by culture. Our suspicion that he was the original source of infection is augmented by the fact that after he had been treated with sulfaguanidine he never again had another attack of the unexplained diarrhea with which he had suffered at intervals up until the epidemic started.

Because of their age, and in most instances also because of their limited mentality, children of this group are much more apt to contaminate others and themselves with fecal material than the older or the higher mental groups. We felt that this was the manner in which the epidemic was spreading, but isolation of those actively ill failed to stop the spread of the epidemic. On the tenth day of the epidemic the disease first

appeared on the third floor, and on the twelfth day a nurse became ill with typical symptoms of the disease. On the fifteenth, because no decrease in the spread of the disease was noted, it was decided to give sulfaguanidine to all the children and to all the personnel willing to take it, and this willingness was unanimous.

PROPHYLACTIC DOSAGE

A brief search of the literature on the drug was made as soon as prophylactic use was considered, but I was unable to discover any precedent on which to base a scheme of dosage. Consequently an arbitrary dosage schedule was used on the following rationale. It, as is indicated by the best works, the absorption of sulfaguanidine is negligible, then its concentration in the bowel is dependent on the dosage and volume of intestinal content in which a given dose is suspended or dissolved. The concentration at a given point anywhere in the bowel will be dependent on two factors only—the dosage per unit of time, and the volume of intestinal content passing that point per unit of time, provided sufficient time has elapsed to bring the concentration up to a fairly good equilibrium.

It is apparent to most of us who see a great many children intimately that the normal volume of intestinal content per day as indicated by the volume of feces excreted is on the average equal to the amount passed by the average adult. For this reason it was decided to give the same dosage to all persons receiving the drug prophylactically, with no consideration of their size or weight.

On the same rationale, the dosage for a normal person with a comparatively small volume of large intestinal content would be considerably smaller than the dosage for a child weighing only one third as much but with an active diarrhea. It is not forgotten that diarrhea is largely due to lack of resorption of water in the large bowel and that therefore concentration of the drug in the small intestine when given prophylactically was considerably less than when the drug was given therapeutically.

Arbitrarily, then, it was decided to give each person in the building not suffering with dysentery a 0.5 Gm tablet of sulfaguanidine three times a day. The prophylactic administration started at noon on the fifteenth day of the epidemic, and we were fortunate in having the cooperation of every employee in the building. The drug was given in this dosage to 31 children who were still well and to all employees in the building part or full time. This meant that a total of approximately 50 persons took the drug prophylactically.

RESULTS OF PROPHYLAXIS

Following the institution of the prophylactic use of the drug, 1 child became ill with the typical signs and symptoms of bacillary dysentery. This case developed within one hour after the first prophylactic dose was given. His dosage was stepped up to the therapeutic level and he was symptomless in thirty-six hours. After this not another child became ill, and within forty-eight hours the nursing problem, which had been very acute for nearly two weeks, no longer existed as a major problem. The chart shows graphically how the nursing problem was eased through the sudden cessation in the development of new cases, combined with the continued recovery of children under treatment. The effect of giving sulfaguanidine in very small doses prophylactically seemed perfectly obvious, especially to the nurses who had been coping with a continuous siege of diarrhea for two weeks.

Four days after the full recovery of the child who became ill last, the prophylactic dose was stopped for all individuals. There were no further signs of the disease in any one in or connected with the building.

No toxic signs nor subjective symptoms were noted in any of the patients or in any well persons taking sulfaguanidine prophylactically.

Stool cultures were repeated ten days after and three weeks after full recovery of the last child in whom a positive stool culture had been found. These were all negative. Culture was again repeated several months later on the boy whom we suspected of being the source of the infection and this was negative. The boy remained well and still remains so a year later, although prior to the epidemic he had been having recurrent bouts of diarrhea at frequent intervals for three or four months.

AGGLUTINATION TESTS

Blood from all patients, all children not infected (with the exception of one from whom it was very difficult to get blood), 18 nurses and teachers and 1 nurse who had had the infection was taken from the veins one week after cessation of the epidemic. Each blood serum was agglutinated against four dysentery strains of organism, namely Flexner, Hiss, Shiga and Strong. Six titer dilutions were used: 1/20, 1/40, 1/80, 1/160, 1/320 and 1/640.

Results Obtained with Original Cultures of Three Children

Patient	Sonne	Flexner	Shiga	Hiss
B B	++	++	0	++
B M	++	0	+	0
J D	++	0	0	0

Following this, the original cultures of 3 children which had been saved were used for agglutination against Sonne, Flexner, Shiga and Hiss strain serums. The results given in the accompanying table were obtained which strengthened our conclusion that we were dealing with the Sonne strain.

SUMMARY AND CONCLUSIONS

1 A rapidly progressing epidemic of bacillary dysentery among mentally handicapped children receiving the best of care was stopped abruptly by the prophylactic use of sulfaguanidine in all well children and personnel in the building after other segregation and treatment methods had failed. The dosage for each subject whether adult or child was 0.5 Gm three times a day by mouth. Similar use has not been mentioned in any literature found.

2 In a comprehensive review of the literature on sulfaguanidine it was noticed that in all reports of reactions of any serious degree the drug was used for patients who were known to have intestinal ulceration or in diseases in which it is usual to expect breaks in the continuity of the intestinal mucosa. I believe it is dangerous to use the drug in the presence of breaks in the intestinal mucosa.

This opinion does not necessarily apply to the use of the drug in the presence of breaks in the intestinal mucosa such as repaired operative incisions in the intestinal wall which have been closed and present no considerable area of denuded wall for absorption.

3 No toxic signs or symptoms of any kind were noted either among our ill patients or among those receiving the drug therapeutically. This is in agreement

with most other writers who have used the drug for bacillary dysentery.

4 Used therapeutically, the drug was dramatically successful in every case in which it was used.

5 Because it is felt that other papers have established the effectiveness of the drug used therapeutically, case reports and charts which had been prepared from them are here omitted.

MALIGNANT LEUKOPENIA SUCCESSFULLY TREATED WITH SULFAPYRIDINE

ROBERT HEILIG, M.D.

AND

S. K. VISVESVAR, M.B.B.S.

MYSORE, SOUTH INDIA

In this country urinary tract infections are much more frequently seen and in our malnourished, multi-infected patients of a far more serious prognosis than literature would lead one to expect.¹ The introduction of the sulfonamide compounds into the therapy of coliform group infections considerably improved the outlook. And yet the gravest of these cases those showing a leukopenia remained excluded from the beneficial and even life saving effect of this treatment because of the clinical rule that a diminished number of leukocytes excludes the use of the sulfonamides. Such patients being usually severely anemic and refractory to methenamine and pentose nucleotide, had a mortality of approximately 100 per cent a fact to which the local difficulty of getting blood donors contributes. In the literature available here only 2 cases of leukopenia and acute agranulocytosis were found² in which along with pentose nucleotides and blood transfusions sulfathiazole was used successfully.

The following 2 cases may show that a trial with sulfapyridine without any additional medication might change the hitherto apparently hopeless prognosis.

CASE 1—H. R. a man aged 45 a Hindu was admitted to our hospital on Oct 10 1942 in an irrational and delirious state. His attendant stated that eight days of a continuous high fever with a rigor on the first day preceded the admission. The heart and lungs showed no pathologic signs. The blood pressure was 115/85. The liver and spleen were not enlarged. The prostate gland was moderately enlarged and of increased consistency. The nervous system showed nothing abnormal. Urinalysis showed albumin 2 plus sugar absent and microscopically red blood cells 2 plus leukocytes 2 plus and granular casts 2 plus. Culture of the urine yielded *Pseudomonas*. The leukocyte count was 15,600 and the differential picture neutrophils 84 per cent and lymphocytes 14 per cent. Blood urea was 55 mg. Malarial parasites were not found. The malaria flocculation test was negative. The Widal test was negative (on admission and six days afterward). The Wassermann Kahn and Klim reactions were negative. The pulse rate was 105 to 120. The temperature was 102.5 F dropping to normal after two days and remaining so for a fortnight. During this afebrile period the patient was treated with intravenous injections of dextrose and methenamine. His delirious condition subsided and he became rational and cooperative. He still showed signs however of a severe toxemia the tongue was dry and heavily coated the pulse was feeble and fast.

From the Krishnarajendra Hospital and Medical College University of Mysore.

an exudative endocytitis developed and the pathologic urinary findings persisted. Seven days after admission (October 18) the leukocyte count was 7,400 with the differential picture as follows: neutrophils 82 per cent, lymphocytes 15 per cent, large monocytes 2 per cent, eosinophils 1 per cent. After another week (October 25) a rigor set in and the temperature rose to 102 F, subsequently the malarial flocculation test became positive and duly quinine was administered by intravenous injection. In spite of this therapy after an interictal interval of only three days, another rigor occurred and again the temperature reached 102 F (October 28) with small intermittences, remaining on this level for three days at the end of which time it rose to 103 F (October 31). While the fever lasted the signs of toxemia gradually increased, leading to a comatose

been normal since November 2 and remained normal except for two minute rises in the next six weeks, at which time the patient was seen the last time (December 15). The whole course consisted of 14 tablets of sulfapyridine and lasted for three and one-half days. Apart from nikethamide, no other treatment was used from the moment that the first sulfapyridine tablet was given. The surprising rise of the leukocytes to 9,375 with 58 per cent neutrophils on November 5 and to 8,750 with 73 per cent neutrophils on November 11, ten days after the sulfapyridine treatment was started, is shown with further observations in table 1. Simultaneously the patient recovered quickly, the urine became normal in all respects and four weeks after having reached a seemingly hopeless condition the patient was discharged, fit for resuming his work.

condition with deeply clouded consciousness, passing of urine and feces in bed and a pulse hardly palpable with a rate of 136 a minute. At this stage the leukocyte count was 2,600 with a differential distribution of 4 (1) per cent neutrophils, 81 per cent lymphocytes, 7 per cent large monocytes and 8 per cent eosinophils. All kinds of circulatory stimulation proving of no avail and the general condition rapidly deteriorating, we decided, in spite of leukopenia and granulocytopenia, to try sulfapyridine, giving 1 tablet every six hours (October 31). The next day, after administration of 4 tablets, the highest temperature was 99.8 F against 103 F the previous day, the leukocyte count rose to 3,750, the neutrophils to 12 per cent, after another 4 Gm within the next two days to 20 per cent with a total amount of 5,800 (November 3). At this time the patient was fully conscious and rational and asking for food, the pulse rate was 80 to 88 and the temperature had

CASE 2—J. L., a woman aged 30, a Hindu, admitted to our hospital on Nov. 26, 1942, gave a history of diarrhea, pain in the abdomen, rigor and fever off and on for the last year. She was highly emaciated and moderately anemic. But apart from one rise up to 101 F on the third day of hospitalization her temperature remained normal for eight days, and during this period only one thick pasty stool was passed every day. Clinical and radiologic examinations showed that the heart and lungs were normal. A fluoroscopic investigation of the stomach with barium sulfate could not be performed because of her extreme weakness. A barium sulfate enema showed diminished haustration of the descending colon. The liver was not palpable, the spleen was slightly enlarged but malarial parasites were not found and the malaria flocculation test was negative. The pelvic organs showed no pathologic changes. The tuberculin test (Mantoux) was negative. A tract of

test meal showed achlorhydria (free hydrochloric acid 0 total acidity 0 to 10 mean values 0 to 10). The stools showed nothing abnormal on microscopic examination and no pathogenic micro-organisms on culture. The urine showed traces of albumin a few erythrocytes and a fair amount of pus cells (2 plus) culture of the urine yielded *Aerobacter aerogenes*. Analysis of the blood revealed 1,200,000 red cells showing anisocytosis the hemoglobin level 22 per cent (Sahli) and color index 0.9. Leukocytes numbered 2,400 with a differential count neutrophils 55 per cent and lymphocytes 45 per cent six days later the leukocytes numbered 2,500 with a similar differential picture. The sedimentation rate was 24 mm the first hour and 68 mm the second hour.

On the ninth day after admission (December 4) when the diet which consisted of wheat congee and buttermilk was changed to boiled unpolished rice and buttermilk the patient had three loose bowel movements and the temperature rose to 100 F the following day the diarrhea increased and accompanied by two rigors the temperature rose twice to 104.5 F. Plain rice seed diet controlled the bowel action within twenty-four hours but in spite of intravenous injection of quinine and of methanamine a decidedly intermittent fever persisted for six consecutive days varying every day between 100 and 104 F the sleep was almost regularly being ushered in by a rigor. The urine showed innumerable pus cells which formed a thick creamy sediment though on culture again only *Aerobacter aerogenes* was growing. The patient was unable to speak understandably the tongue was extremely dry and was covered with brown fur the pulse which was hardly palpable reached a rate of 134. On the sixth day (December 10) at this high febrile condition the leukocyte count was 1,800 with 18 per cent neutrophils 79 lymphocytes and 3 per cent eosinophils. The erythrocytes numbered 900,000 with hemoglobin 16 per cent (Sahli). The prognosis seemed to be so gloomy that we thought it justifiable to take every risk that might give the patient the slightest chance of overcoming this septicemic condition which certainly originated from the urinary tract. In spite of the severe leukopenia and granulocytopenia a course of sulapyridine was started with 1 tablet every six hours the doses being gradually reduced until 20% tablets (10.25 Gm) had been given within six days. The result was most astonishing. After 4 tablets of sulapyridine the temperature came down from 104 F on December 10 to normal on the following day and the patient remained perfectly afebrile except for one single rise to 100 F on December 12 up to Jan 28 1943. Table 2 shows how the leukocyte count increased from 1,800 on December 6 to 2,500 on the 12th to 3,700 on the 13th and to 10,300 on the 17th and was stabilized at about 7,000 during the following month the percentage of neutrophils simultaneously rose from 18 to 26 36 and 77 within seven days remaining constant at about 75 to 80 per cent.

It was a most impressive experience to see how quickly the apparently moribund patient turned to a convalescent with a well sustained pulse though still at an increased rate a rapidly clearing moist tongue and improving appetite. To stimulate the regeneration of the red blood picture which by the end of the sulapyridine treatment showed 1,100,000 erythrocytes and 20 per cent hemoglobin (Sahli) a series of fifteen injections of crude liver extract (Pronaemia) was given accompanied by dried yeast 1 teaspoon twice a day. On January 13 the figures were 2,500,000 red blood cells 40 per cent hemoglobin (Sahli) 6,900 leukocytes 74 per cent neutrophils and 25 per cent lymphocytes. The sedimentation rate was 7 mm the first hour and 17 mm the second hour. Without administering any other treatment the condition of the urine improved considerably though it had not become normal on January 15 albumin was absent and a fair amount of leukocytes was present culture yielded a few colonies of *Escherichia coli*. The bowel action remained normal throughout the entirely uneventful convalescence and even the gastric function improved considerably. On January 16 a fractional test meal showed free hydrochloric acid 0 to 28, total acidity 8 to 46, mean values were free hydrochloric acid 11 and total acidity 22 as against achlorhydria on admission.

COMMENT

It is a generally accepted clinical rule that the sulfonamides are strictly contraindicated in all cases of leukopenia especially when a granulocytopenia is present. This rule is based on the fact that members of the sulfonamide group tend toward diminishing the number of leukocytes in general and the granulocytes in particular to such an extent that fatal consequences due to acute agranulocytosis have been reported in numerous instances. This danger is supposed to threaten whenever full doses of one of these compounds are used so much so that leukocyte and differential counts should be performed at short intervals and the application of these drugs stopped at once when the total amount of white cells or the percentage of neutrophils shows a tendency to decrease.

Furthermore it is well known not only that sulfanilamide sulapyridine and other sulfonamide compounds interfere with the leukopoiesis but also that the red blood cell count occasionally shows such a reduction that blood transfusions might be required.³ Quite recently Chaudhuri⁴ found that therapeutic doses of sulfanilamide and sulapyridine in monkeys cause 'a moderate and progressive anemia' and 'a consistent decrease of leukocytes'. Nevertheless the reasoning might be justified that a toxic arrest of the leukopoietic activity of the bone marrow causing leukopenia and granulocytopenia could be counteracted and the normal marrow function restored if one succeeded in eliminating the source of toxin production. Thus the question arises whether it is probable that the sulfonamides would exert their bacteriostatic action which inhibits the further release of toxins more rapidly than their paralyzing influence on the bone marrow. Dameshek and Wolson⁵ found in 2 cases of acute agranulocytosis that sulfathiazole did no harm and that it might have been of value in combating the secondary sepsis, although no definite proof for the latter opinion could be presented because it was given in addition to transfusions and pentnucleotides. So far as 2 cases can show small doses of sulapyridine are capable of improving the rapidly declining leukopoiesis if the infective organisms responsible for the severe toxemia respond promptly to the drug. In our cases such a response was established—apart from the changes in the blood picture—by the fact that the fever subsided immediately and the general condition which prior to sulapyridine medication apparently precluded any hope improved so speedily and completely without the employment of any other treatment that a spontaneous or chance recovery obviously was out of the question.

The course of events leading to this development, unexpected in several aspects could be reconstructed and the origin of the toxemia traced in the following way. In the first case a hypertrophied prostate gland which as the patient later stated had caused typical complaints for the past one year caused urinary stagnation with a subsequent infection of the urinary tract. A tendency to a low leukocyte count is not rarely seen in coliform group infections¹ so that an unusually heavy infection such as was proved in this case by the

onset with a rigor, the high fever and the delirious condition, might have turned the initial leukocytosis to leukopenia which renders the system defenseless against a further invasion and unrestrained multiplication of all kinds of pathogenic micro-organisms. The second patient suffered from diarrhea which lasted for one year up to her admission. Though it recurred only on the ninth day of her stay in the hospital and lasted for a few days, easily controlled by Plantago seed diet it is significant that this short attack of diarrhea the very next day was followed by the heaviest febrile attack, with two rigors the temperature reaching 101.5 F twice within one day. The explanation is that during the chronic diarrhea which preceded the patient's hospitalization a chronic infection of the urinary tract, proved microscopically and bacteriologically on admission was established, owing to the increased permeability of the affected mucous membrane of the colon. The acute diarrheal relapse certainly was due to an increased virulence of the intestinal bacterial flora which invaded the urinary tract in force and, most probably, simultaneously entered the systemic circulation. Proof of the former process is the enormous increase of pus cells (4 plus) in a catheter specimen of the urine, the latter—the development of a septicemia—is almost ascertained by the occurrence of six rigors in eight days of high fever, uninfluenced by intravenous administration of quinine. The close connection between diarrhea and subsequent urinary tract infection was experimentally established by Leishman⁶ and is noticed in almost all of our diarrhea cases, especially in women. In contrast to the first case, leukopenia of 2,400 to 2,500 leukocytes per cubic millimeter with a relative lymphocytosis already present was found on admission. The further development clearly shows that this white blood cell picture was due not to some constitutional peculiarity but only to the urinary tract infection, the leukocyte count subsequent to the successful treatment of the septicemia being constant at about 7,000 with a normal differential picture. It is noteworthy that the red blood cell count did not improve simultaneously with the leukocytes but required administration of crude liver extract. In both of these cases small doses (1.5 to 2.5 Gm) of sulfapyridine succeeded in cutting short the course of the fever and further administration of 2 Gm a day, making a total of 6.25 Gm and 10.25 Gm respectively, in keeping the patients afebrile. It is highly improbable that such doses should have been sufficient to achieve sterilization of the heavily infected urinary tract, the more so as in case 2 *Escherichia coli* was found in the urine after one month of afebrility, normal bowel function and general well-being. The explanation of the successful medication obviously is that the drug, exerting its generally recognized bacteriostatic action, stopped further bacterial multiplication and prevented a renewed invasion of the circulation as well as further production of toxin, thus enabling the patient's defense mechanisms to deal with the bacteria which already were present in the system when the treatment was started.

When these cases were presented⁷ the discussion hinged on whether the development of leukopenia was not precipitated by the intravenous use of quinine and methenamine with sodium salicylate and caffeine with sodium salicylate (Pyelopurin). For the investigation

of this question 4 patients with particularly severe malarial and 4 with highly febrile urinary or biliary tract infection, all of them in a very low condition, were selected and treated with full doses of quinine or the proprietary methenamine mixture respectively by the intravenous route.

In each of these cases a total leukocyte count and differential picture have been determined before and twelve to twenty-four hours after conclusion of a course of either five quinine injections, containing 35 grains (2.3 Gm) of quinine dihydrochloride, or of 5 ampules of "pyelopurin intravenous," each of them containing methenamine 30 grains (2 Gm), sodium salicylate 12 grains (0.8 Gm) and caffeine with sodium salicylate 3 grains (0.2 Gm). In 2 of the cases in which quinine was given, the leukocyte count increased, in the other 2 it remained unaltered. The proportion of neutrophils showed variations of ± 10 per cent with a maximum of 80 and a minimum of 60 per cent after treatment. Similarly insignificant were the changes following medication with the methenamine mixture. In addition to our 8 control patients, the second of our 2 leukopenia patients (J. L.) received a course of five intravenous injections of the methenamine preparation when after one month of well-being *Escherichia coli* was found in her urine, on conclusion of this medication (January 25) the leukocyte count was 6,800, the differential picture 72 per cent neutrophils, 27 per cent lymphocytes and 1 per cent eosinophils. These results make it highly improbable that in our cases leukopenia and granulocytopenia should have been due to doses of quinine or methenamine with sodium salicylate and caffeine with sodium salicylate which were smaller than those used in the control cases, though it cannot be excluded that in rare instances of hypersensitivity against these compounds and a constitutional weakness of the leukopoietic apparatus such a reaction might develop.

SUMMARY

Two cases of highly toxic infections of the urinary tract were characterized by considerable leukopenia and granulocytopenia.

In both of them small doses of sulfapyridine, without any other treatment, brought about a rapid improvement of the general condition especially of the white blood picture, leading to recovery from seemingly hopeless conditions.

Eight control cases were studied to see whether quinine or the methenamine-sodium salicylate caffeine with sodium salicylate mixture administered by intravenous injection diminishes the amount of leukocytes or the percentage of neutrophils. Such changes were not seen in these cases.

Vinegar—If a saccharine liquid (e. g. cider) which has been fermented by yeast is left undisturbed and exposed to a limited supply of air, it gradually becomes acid and eventually turns into vinegar. Vinegar formation is a second fermentation which follows alcoholic fermentation. Bacteria are the agents involved and they oxidize ethyl alcohol, first to acetaldehyde and then to acetic acid. The so called mother of vinegar, *Mycoderma aceti*, as Pasteur named it, consists of a number of species of bacteria rather than a single organism. These bacteria produce a slimy, gelatinous growth on the surface of the liquid, which falls to the bottom and is succeeded by a new film. The bacteria contained in the film bring about the conversion of the alcohol into acetic acid.—Peterson, William F., Skinner, John T., and Strong, Frank M., *Elements of Food Biochemistry*, New York, Prentice-Hall Inc., 1943.

THE FREQUENCY OF INADEQUATE
ANTIDIPHTHERIA IMMUNIZATION

IN AN INFECTIOUS DISEASE HOSPITAL

JESSE G. M. BULLOW, MD

Visiting Physician Harlem Hospital Visiting Physician Willard
Parker Hospital Clinical Professor of Medicine New York
University College of Medicine
AND

MARGARET SCANNEL, MD

Resident Physician Willard Parker Hospital
NEW YORK

A positive Schick test is evidence that there is not sufficient circulating antitoxin to prevent the action of injected diphtheria toxin on the skin. Sufficient humoral immunity may be present to insure a negative Schick test after an attack of diphtheria or after active immunization, but the amount and duration of immunity varies in different people. Even a partial immunization may stimulate the immunity mechanism so that it reacts more actively with the restimulation of disease and accordingly is advantageous. However, a history of immunization unless checked by a dermatologic test, should not be used to exclude the diagnosis of diphtheria in the presence of clinical signs of the disease.

In order to determine the proportion of Schick positive children among those previously immunized, the parents of all children admitted to Willard Parker Hospital for diseases other than diphtheria during the months of June through September 1941 were carefully interrogated regarding immunizing procedures.¹ Willard Parker Hospital is a contagious disease hospital in New York City where Schick and Dick testing are routine procedures on admission. The group studied consisted of children of both sexes from 1 to 16 years of age. Forty-eight or 24 per cent of the 200 previously immunized patients were Schick positive. The age and sex distribution of the positive reactors did not differ from that of the group tested. In none of the infectious diseases was there a disproportionate number of positive Schick reactors. Measles has been observed to produce a diminished tissue resistance to the diphtheria toxin but no statement based on this study can be made on the especial effect of measles on the diphtheria protective mechanism after immunization, because among 2,068 patients admitted for measles in the first six months of 1941 there were only 2 patients with clinical diphtheria. One had received toxoid and one had not received any immunization.

During the eighteen month period extending from Jan. 1, 1940 through June 31, 1941 there were 88 patients admitted to Willard Parker Hospital for clinical diphtheria. Of these patients 29, or 32.9 per cent had previously been immunized. These patients had received from one to four injections of an immunizing agent. Subsequent Schick tests had not been performed on any. In 5 patients, or 5.6 per cent no definite history in reference to immunization could be obtained. In 54 patients, or 61.4 per cent, no attempt to immunize had been made. The location of the membrane was uninfluenced by immunization, as shown in the accompanying table.

The immunized patients were not as severely ill as those in whom immunization had not been attempted.

This study received support from the Littauer Pneumonia Research Fund.

¹ Because of the vagueness of parents' knowledge of technical procedures all types of immunization have been considered together.

In the nonimmunized group there were five deaths, whereas there were no deaths among the patients who had received some immunizing injections, even though they were insufficient to prevent the disease. The average duration of illness before admission was the same in the two groups. There was considerable delay in the administration of diphtheria antitoxin in some patients because when there was a history of injections the physicians in attendance or in outpatient departments assumed that the throat infection was not due to diphtheria. The fact that patients may receive prophylactic injections without developing complete immunity is not sufficiently recognized. After partial immunization the illness may be very severe and clinically typical. The diagnosis of diphtheria must be made from the constitutional and local response to the toxin. Antitoxin should be given without delay. We give here an illustrative history of a patient from whom diphtheria antitoxin was temporarily withheld.

REPORT OF CASE

P. C., a girl aged 3 years, admitted to Willard Parker Hospital on March 28, 1941, had received 1 cc of toxoid on Feb. 15, 1940 and 1 cc on March 1, 1940. There had been no subsequent Schick test. Four days before admission, measles developed. On March 26 a croupy cough and slight retractions were present. On this day the croup was attributed to measles and antitoxin was withheld by the family physician because of the history of immunization. This physician saw the patient on

Location of Membrane in Immunized and Nonimmunized Patients

	Immunized	Per Cent	Nonimmunized	Per Cent
Nasal	5	17.2	15	27.7
Pharyngeal	16	52.1	30	45.1
Laryngeal	1	3.4	1	1.6
Combined	7	24.1	12	22.2
	29	59.8	58	59.5

two occasions including the day of admission to Willard Parker Hospital. She was seen at the outpatient department of a large hospital on March 28 and antitoxin was not given then because of the history of immunization. The child was brought to Willard Parker Hospital because of the measles. The croupy cough increased and she was very restless. She was acutely ill, toxic and hoarse with moderate respiratory distress. There was a fading measles rash. The cervical lymph nodes were enlarged but not tender. A dirty, thick, grayish membrane was seen on both tonsils, uvula and pharyngeal wall and over the supraglottic and subglottic areas. The heart was rapid but the tones were of good quality and regular. The temperature was 102.8 F, the pulse rate 124 and the respiratory rate 22. A direct laryngoscopy was done and the larynx was suctioned. Immediately after aspiration of the larynx the respiratory distress disappeared and the voice became less hoarse. Antitoxin 20,000 units intravenously and 40,000 units intramuscularly was given with epinephrine. On the second hospital day the patient coughed up several large pieces of membrane. On the thirteenth day bilateral catarrhal otitis media developed.

SUMMARY

1. Twenty-four per cent of a sample group of 200 previously immunized patients admitted to an infectious disease hospital for disease other than diphtheria were found to be Schick positive.

2. One third of the patients with diphtheria admitted to Willard Parker Hospital during a year and a half had received partial immunization against diphtheria. Antitoxin had been withheld from some patients with clinical diphtheria because of the history of immunization.

CONCLUSION

1 As measured by a negative Schick test, only 76 per cent of patients admitted to Willard Parker Hospital are effectively immunized by current routine procedures and thus thoroughly protected against the disease

2 The history of immunization against diphtheria should not lead to delay or failure to administer anti-toxin when there is clinical evidence of diphtheria. Unless the Schick test has become and remains negative, immunity should not be assumed

3 Schick tests should be done after immunization so that if necessary the immunization may be fortified by extra dosage

Clinical Notes, Suggestions and New Instruments

PERFORATION OF ESOPHAGUS CAUSED BY FLEXIBLE GASTROSCOPE

REPORT OF CASE WITH AUTOPSY

W. D. PAUL, M.D., IOWA CITY AND
LIEUTENANT (JG) R. H. LAGE, (MC) U. S. N. R.

Endoscopic examination of the stomach with the rigid gastro-scope was a hazardous procedure, and according to Schindler many deaths resulted. With the flexible instrument complications are rare, and only one death has been questionably attributed to its use. Schindler in 1940 reported the results of a questionnaire concerning fatalities in relation to gastroscopic examination. In all, 22,351 gastroscopic examinations were reported. In this series there were eight perforations of the stomach and one of the jejunum, but none of these terminated fatally. One patient died nine days after the examination, but whether the latter was directly responsible for the fatal outcome could not be definitely established. Since this report was published others have recorded complications none of which were fatal.

At the University of Iowa 538 consecutive gastroscopic examinations were done without any complications. The technic advised by Schindler was used both in preparation of the patient and in introduction of the instrument. In the case being reported in which our 539th gastroscopic examination was performed the patient died twenty-four hours after instrumentation.

REPORT OF CASE

G. P., a white man aged 81, admitted to the University Hospital on March 26, 1942 complained of epigastric distress, tarry stools and loss of weight. He had had attacks of epigastric distress, nausea and vomiting most of his life. Three months before admission he noticed tarry stools for a few days. After that time he lost about 22 pounds (10 Kg). A transurethral prostatic resection had been performed in 1937.

Physical examination revealed that the patient was emaciated but was not acutely ill. The head and neck were essentially normal. The thorax was long and narrow and was normal to auscultation and percussion. The heart was enlarged both to

the right and to the left, auricular fibrillation was present and the blood pressure was 106/74 mm of mercury. The cardiac rate was 98 a minute. The peripheral arteries were thickened and tortuous. Palpation of the abdomen revealed tenderness in the epigastrium, but no masses were felt. The left testis was absent. The prostate was moderately enlarged and firm but not nodular. The extremities and reflexes were normal.

Examination of the blood showed a hemoglobin content of 12 Gm, the erythrocyte count was 32 million, the leukocyte count 7,900 and the differential leukocyte count normal. Several urinalyses were negative. The blood Wassermann reaction was negative. A roentgenogram of the chest showed that the heart was enlarged, but the lungs were normal. Fluoroscopic and roentgenographic examination of the stomach disclosed a penetrating ulcer on the lesser curvature. The ulcer measured about 1.5 cm in diameter.

Two days after admission a gastroscopic examination was done. The instrument was passed with ease and depth 1 was readily visualized. The angulus appeared distorted and was pulled to the right. In the midportion of the angulus a triangular defect was seen (Henning's sign). The mucosa was pale, many areas of submucosal hemorrhage were present and mucus adhered to the surface of the gastric mucosa. Just proximal to Henning's sign on the lesser curvature an oval ulcer about 2 cm in diameter was noted. As this lesion was viewed at a tangent the floor of the ulcer could not be accurately visualized. The mucosa surrounding the ulcer was pliable and not edematous, and peristalsis was active in this region. Depth 2 showed a slight amount of atrophic and considerable superficial gastritis. Depth 3 was essentially normal. The diagnosis was benign ulcer on the lesser curvature. The gastroscopic procedure lasted ten minutes.

Four hours later the patient complained of pain in his throat and difficulty in swallowing. Six hours later he had a chill, and his temperature rose to 102 F. Physical examination revealed nothing significant. The next morning the patient was cyanotic and had difficulty in breathing. At this time there was pronounced crepitus over the right side of the neck and the right upper anterior portion of the chest. Dulness was present over the bases of both lungs, and many rales were heard. The patient could not speak above a whisper. In a very short time he became comatose and died. Autopsy showed that the tissues of the anterior and posterior mediastinum and entire pericardium were extremely edematous and the seat of a fulminating cellulitis. The tissues of the neck showed a definite fibrinous exudate. No frank pus was found. The esophagus was normal, and even when air was blown into it no perforation could be found. Both lungs showed an extreme degree of hemorrhage, congestion and patchy pneumonia. A penetrating ulcer 2.5 cm in diameter was present on the lesser curvature of the stomach near the antrum. The organs were essentially normal.

Microscopic sections of the tissues of the neck and upper part of the thorax showed a fibrinous, acute, phlegmonous cellulitis with extreme edema. There was no evidence of localization. The edema and the inflammatory exudate dissected through the tissue septums and even between the individual skeletal muscle fibers. There was no evidence of tissue necrosis. Beta hemolytic streptococci were isolated from these tissues.

COMMENT

We were unable to ascertain why this accident occurred. The instrumentation was exceedingly easy and the patient was very cooperative. At first we thought that the age of the patient was a factor. Since this examination we have completed 500 more without a single complication. In the latter group there were many patients ranging in age from 75 to 83. On two occasions the rubber tip became loose and was lost in the stomach, but neither of these patients showed any trauma either in the esophagus or in the stomach. After the death of the patient the gastro-scope was examined carefully but nothing unusual was found. Even though definite perforation was found at autopsy, it is possible that the tear was very small and was closed by serum or exudate. This is the first known case caused by perforation of the esophagus of a patient with no previous disease of the esophagus or mediastinum.

MALIGNANT MELANOMA OF THE CHOROID WITH EXTENSIVE METASTASIS TREATED BY REMOVAL OF SECRETING TISSUE OF THE TESTICLES

WILLIAM P. HERBST, M.D., WASHINGTON, D. C.

A K. a man aged 69 had a malignant melanoma of the choroid removed on Sept. 29 1939 by Dr. J. B. Griffith. The pathologic report of the specimen which was submitted to Lieut. Col. J. I. Ash, M. C., United States Army, curator of the Army Medical Museum follows:

Gross. The eye has been opened in the horizontal plane. The retina is detached and behind it on one side is a pink mass measuring 16 by 9 mm. which extends from the optic disk to a point midway between the equator and the ciliary body.

Microscopic. Extending from the ora serrata almost to the optic disk is a tumor mass which appears to be breaking through Bruch's membrane in several places. A few thin walled blood vessels are seen. pigment is not discernible. The cells are spindle shaped with oval nuclei round or polygonal with abundant cytoplasm and smaller nuclei. All have prominent nucleoli. The Callender-Wilder classification shows the tumor to be less than 50 per cent argyrophil. fibroid. Intrabulbar extension is not demonstrated.

Diagnosis. Malignant melanoma of the choroid spindle cell subtype B and large and small epithelioid cell. extensive glaucoma secondary early intraocular hemorrhage detachment of retina.

A short time after removal of the eye nodules appeared around the right orbit followed by numerous masses all through and on the surface of the patient's body. On Dec. 26 1942 he was in a state of complete physical exhaustion bedridden and unable to retain food because of nausea induced by a fluid which regurgitated from the pharynx. His liver was enlarged to at least twice its usual size and was nodular. The nodules on the surface of the body varied in size from 3 cm. in diameter to 10 cm.

On December 28 under pentothal sodium anesthesia the secreting tissue of the right testicle and the entire contents of the left scrotum were removed because of the presence of multiple spermatocoeles on that side. His course following this operation was rather interesting in that he had no further nausea and was able to take small quantities of any kind of food that was given to him. There was no more fluid coming from the respiratory tract. There was definite regression of some of the metastatic lesions and no new lesions developed. He seemed to be improving gradually until Feb. 15 1943 at which time he became unconscious while he was asleep and died. Permission for autopsy was not obtainable.

COMMENT

The basis for the indication for this procedure is not clear but the line of thought leading to the suggestion for this form of treatment is as follows:

Farrow and Adair¹ reported disappearance of extensive osseous metastases secondary to carcinoma of the breast in a man following castration.

McClelland² reported a case of extensive generalized metastasis secondary to a testicular tumor in which the removal of the primary tumor and the sound testicle was followed by rapid disappearance of all the metastatic lesions.

Huggins³ made a contribution to the biochemical aspects of orchectomy for carcinoma of the prostate.

In view of these observations I felt that there was a remote possibility of so changing the biochemical status of the patient by removing the testicular tissue that the biochemical soil in which the malignant cells were growing might prove to be unfavorable to their continued expansion and growth.

Since that time there has been another interesting case reported in the literature by George G. Binne⁴. He reported

an extensive metastatic pleomorphic osteogenic carcinoma which almost entirely disappeared following a course of high voltage roentgen therapy combined with the injections of diethylstilbestrol in comparatively large doses. He employed 5.75 and 10 mg. doses daily intramuscularly. This case is not presented with any idea of claiming to comprehend the chemical mechanism involved but simply as an interesting clinical observation.

REFRIGERATION ANESTHESIA IN SKIN GRAFTING

FIFTEEN T. HARRY F. MOCK, JR., MEDICAL CORPS
UNITED STATES ARMY

Refrigeration anesthesia for skin grafting opens a new field for the use of reduced temperatures in surgery. In 27 cases requiring small or multiple small split thickness skin grafts this method was used. Punch grafts could be removed equally well although none were attempted in this series. Results were so satisfactory that this report is submitted for general consideration.

In July 1941 my associates and I began to use refrigeration anesthesia for the amputation of extremities. When an extremity is refrigerated for amputation a tourniquet is always used.

Fig. 1—Ice bag snugly applied to the skin preferably with bandages for two and one-half hours anesthetizes the donor site.

Ordinarily the constriction of a tourniquet is painful. Some of the original workers in refrigeration anesthesia discovered that previous chilling of the tissues with ice bags definitely decreased this discomfort. We corroborated this finding noting also that the skin was completely anesthetized. It was this ability of ice bags to produce superficial anesthesia that led us to attempt the method on donor sites for skin grafts.

TECHNIC

Two hours before operation one or more uncovered ice bags are applied directly to the area from which the skin is to be taken. The number of ice bags required depends entirely on the amount of skin to be anesthetized. Slight pressure deepens the anesthesia so it has been our practice to tie or bandage the ice bags in place. The donor site may be marked and orders left for the nurse to apply the ice bag or bags at the desired time. In hot weather they may have to be refilled but usually they are not disturbed until the surgeon is scrubbed and ready to prepare the skin. The maximum anesthetic effect lasts approximately twenty minutes after the ice bags have been removed.

Many of our operations are not carried out in the operating room. In the ordinary case with a small or moderate defect to be grafted orders are also left to have the necessary instruments in the ward. Then during the course of rounds the

procedure is done at the bedside or in the dressing room. It is amazingly simple—the donor site is cleansed with alcohol, the graft is cut and put in place and dressings are applied.

Preoperative medication is not usually necessary but may be a helpful adjuvant. In this series it was used only for those patients who were apprehensive. They were given morphine sulfate one-half to one hour before operation.

Fig. 2—Cutting the skin graft from the thigh

Complete anesthesia was obtained in 24 of the 27 patients prepared by refrigeration. The 3 patients with incomplete anesthesia complained of a burning sensation when the graft was cut, but it was not sufficiently acute to necessitate another form of anesthesia. In each of these cases we were too hasty and did not allow a full two hours for chilling.

Refrigeration does not noticeably affect the growth of the graft or the repair of the donor site. Complete healing occurred in two to three weeks in almost every case. Successful grafts were obtained in 23 of the cases. The 4 failures occurred in patients whose granulations were infected more than we realized and should more properly be ascribed to our error in judgment than to the method. In 2 of these cases subsequently suc-

Fig. 3—Placing the skin graft on a small, ulcerated area on the leg

cessful grafts were obtained with the same technic. In the other 2 there was slow healing by granulation and epithelialization.

SUMMARY

A new use of reduced temperatures in surgery, namely anesthesia of skin graft donor sites by refrigeration, is recommended because it is simple, time saving and efficient. It has been used in 27 cases.

EXPLOSIVE INJURY DUE TO SOLID CARBON DIOXIDE

W. ORR GOEHRING, M.D., PITTSBURGH

Carbon dioxide is of increasing importance commercially. Many of its uses rely on its rapid expansion when released from a compressed state.¹ That this expansile force of solid carbon dioxide, the familiar "dry ice," is tremendous can perhaps best be appreciated by the realization that a rifle is now being manufactured using crushed "dry ice" as the propelling force. One loading is sufficient to "fire" 1,800 bullets of 0.22 caliber.² It was surprising, therefore, that reports of explosive injuries due to solid carbon dioxide are not to be found in the literature. Indeed, reports of all types of injuries are meager, though Stout³ and Som and Neffson⁴ have each drawn attention to the danger of aspiration. That the continued availability of "dry ice" to enterprising children remains a danger is illustrated by the case reported here.

REPORT OF CASE

K. L., a school boy aged 14, was brought to Columbia Hospital the evening of Dec. 31, 1942 with the history, later verified, that he and a chum had purchased a small block of "dry ice" at a local dairy store. This they had placed in a 5 gallon garden spray can in order to extinguish small fires with the vapor by suffocation. To increase the rate of vaporization, the can was partially filled with water. While they were in the process of building another fire the can exploded, the upper edge striking the patient in the face, knocking him down and traveling a distance of 50 feet. Further history was not significant.

On admission the patient was semiconscious and in mild shock, with a large, gaping laceration of the face. The blood pressure was 115/80, the pulse rate 86 a minute and the temperature 98 F. Roentgen examination of the skull showed no fracture of the vault. The patient was promptly taken to the operating room for debridement and reconstruction. Intravenous anesthesia with 2.5 per cent solution of sodium pentothal was administered along with an infusion of isotonic solution of sodium chloride and 300 cc of citrated whole blood. Further examination showed a deep laceration extending down along the left side of the nose, across the columella and out across the right cheek to a point on a line with the malar prominence. The upper flap gaped, the laceration having extended internally upward to the infraorbital ridges of the maxillary bones, which were fragmented. Both antrums were laid open, the nasal bones, the vomer and the ethmoid plate were comminuted. The inferior and middle conchae were shattered. Three upper incisor teeth were missing, the fourth had been thrust back up into the premaxilla, which, along with the superior alveolar process, was shattered. There was moderate bleeding from a branch of the right facial artery. The parotid duct and main branches of the facial nerve, apparently, were not exposed. Both orbits appeared uninjured, though there was extensive periorbital swelling and hemorrhage. All bony fragments were replaced. The nares were reconstructed with some difficulty over soft rubber tubing. Five Gm of sulfathiazole powder was sprinkled about the wound prior to closure. Fine chromic catgut was used for buried sutures and number 70 white cotton thread for skin sutures. Petrolatum gauze was inserted into the external nares as packing to control oozing. A prophylactic dose of tetanus antitoxin was administered.

The next morning, twelve hours after admission, the patient regained consciousness, and oral administration of sulfathiazole in doses of 1 Gm every four hours was begun. The further course of the patient was most gratifying. The highest temperature elevation was to 100.8 F rectally on the first postoperative day, after forty-eight hours it was normal. He

parotidum packs were removed the morning after operation and the soft rubber tubing twenty four hours later. There was a moderate amount of sero sanguineous nasal drainage never odorous. The nares remained patent. On the sixth day there was a small amount of purulent drainage from a tooth socket. Administration of sulfathiazole was kept up for ten days a blood level of 3 mc. per hundred cubic centimeters being maintained. Locally sodium perborate in the form of a paste was used in the mouth and a suspension of sulfathiazole in the nose. As the intense periorbital edema subsided it was apparent that the patient had a partial third nerve paralysis as evidenced by diplopia, loss of convergence and partial ptosis of the right lid. Improvement was pronounced and by the time the patient left the hospital on the seventeenth day after admission convergence was much improved and the ptosis less. In the week following the diplopia and ptosis cleared, the sense of smell and the sneeze reflex both of which had been lost likewise were recovered. When last examined three months after the accident both nares were patent and the cosmetic result was satisfactory.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
ALVIN F. SMITH, M.D., Secretary

DOSAGE OF VITAMIN PREPARATIONS

At various times the Council has given consideration to excessive and indiscriminate use of vitamin preparations by the general public. There has been no concern over any danger in such usage in doses which the Council would consider for therapeutic recommendation but it is quite apparent that large numbers of people have been using pharmaceutical preparations of vitamins far in excess of what would be expected to be of real benefit. This first became apparent in considering the large dosages recommended for vitamin A and D preparations when these vitamins became available at a relatively low cost. This prompted the Council to restrict the acceptance of vitamin A and D preparations recommending high dosages of vitamins A and D to preparations advertised only to the physician and the following statement of policy was adopted:

Vitamin A and D preparations are accepted with dosages in excess of 10,000 units of vitamin A or 1,000 units of vitamin D if the products are advertised only to the physician and the dosage statement indicates that the dose prescribed provides more than a prophylactic dose of the vitamin.

The Council decided that the principle involved should be applied uniformly to all vitamin preparations and accordingly adopted the following recommendation:

'That acceptable vitamin preparations which supply in each unit (tablet, capsule, etc.) or in the recommended daily intake more than three times the minimum daily requirements set forth in regulations under Sec. 403 (j) of the Food Drug and Cosmetic Act will be accepted if they are advertised only to the physician.'

For the past few years there has been some uncertainty with respect to the type of dosage statement that would meet the requirements of the FDC act for vitamin preparations, particularly those which provided a relatively high dosage. The Council was advised that the statement 'Caution: For therapeutic use only, to be used by or on the prescription of a physician' for a thiamine preparation which supplied doses larger than 3 mg. daily would meet the requirements of that act and therefore such a statement has been required. Further consideration has been given to this problem particularly because use of the term 'caution' had a connotation which did not seem desirable for vitamin preparations. The Council has received assurance that this caution statement will no longer be required and that the following type of statement is acceptable for thiamine preparations which supply more than 3 mg. per tablet:

Dose: One tablet daily, or as prescribed by the physician. This dosage is in excess of the quantity needed for prevention of thiamine deficiency.'

The Council voted that this type of dosage statement be made applicable to vitamin preparations which supply in each unit (tablet, capsule, etc.) or in the recommended daily intake more than 12,000 units of vitamin A, 1,200 units of vitamin D, 90 mg. of vitamin C, 3 mg. of thiamine hydrochloride, 6 mg. of riboflavin or 30 mg. of nicotinic acid.

The Council has prepared the following suggested label statements to carry into effect the foregoing recommendations. Labels for thiamine hydrochloride are envisaged in the statement given but it will apply equally well to other vitamin preparations.

STATEMENTS REQUIRED ON MAIN PANEL

FOR PREPARATIONS SUPPLYING MORE THAN THREE TIMES THE MINIMUM DAILY REQUIREMENTS

Quantity of contents	50 tablets
Common or usual name	Thiamine Hydrochloride Tablets
Quantity of vitamin in tablets consumed daily	10 milligrams
Adequate directions for use	Dose: One tablet daily, or as prescribed by the physician. This dosage is in excess of the quantity needed for prevention of thiamine deficiency.
Name and place of business	John Doe 550 Broad Street Chicago, Illinois

FOR PREPARATIONS SUPPLYING THREE TIMES THE MINIMUM DAILY REQUIREMENT OR LESS

Quantity of contents	100 tablets
Common or usual name	Thiamine Hydrochloride Tablets
Quantity of vitamin in tablets consumed daily	One milligram
Dose: This is optional	
Proportion of minimum daily requirement	One tablet will supply the minimum daily requirement for an adult.
Name and place of business	John Doe 550 Broad Street Chicago, Illinois

Council on Foods and Nutrition

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.
OFFICE OF THE COUNCIL.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939 p. 295)

PROTEIN SUPPLEMENTARY FOODS

Under certain conditions it is desirable to give a high protein intake to patients or for other reasons it may be desirable to have available a suitable protein food. Among those products which are available for this purpose are preparations of casein and more recently there have been made available hydrolyzed protein products.

The following product has been found acceptable by the Council
Arlington Chemical Company, Yonkers, N. Y.

AMINOIDS PLAIN AND CHOCOLATE FLAVORED—protein food supplements consists of hydrolyzed dried powdered beef, wheat gluten, dried skim milk and dried brewers' yeast. Cocoa is added to Chocolate Flavored.

Method of Manufacture—The ingredients are suspended in water and the pH is adjusted to proper level and digested with natural proteolytic enzymes. The digest is sterilized by boiling for thirty minutes and the undigested residue filtered off. The filtrate is then concentrated and dried in vacuo. The dried material is tested for total nitrogen by a modified Kjeldahl-Gunning method and for ash by incineration. Based on the test for total nitrogen the calculated amounts of aminoacetic acid and carbohydrates are added. For Aminooids with chocolate flavor the proper amount of cocoa is added to give the desired flavor. The whole is then mixed thoroughly, passed through a 16 mesh sieve and packaged. Samples of each batch of finished product are rechecked for total nitrogen and amino nitrogen.

ANALYSIS (submitted by manufacturer)—PLAIN Amino acids and Polypeptides derived from milk, beef, wheat and yeast equivalent to proteins (N \times 6.25) 44.5%, carbohydrates (dextrose, lactose, maltose, sucrose) 43.3%, ash 6.3%, moisture 5.9%.

CHOCOLATE FLAVORED—Amino acids and Polypeptides derived from milk, beef, wheat and yeast equivalent to protein (N \times 6.25) 44.5%, carbohydrates (dextrose, lactose, maltose, sucrose) 35.3%, ash 6.3%, chocolate flavor 8.0%, moisture 5.9%.

Calories—3.5 per gram, 99.4 per ounce on Aminooids (Plain)

SATURDAY JUNE 26, 1943

WAGNER-MURRAY-DINGELL BILL FOR SOCIAL SECURITY

Elsewhere in this issue appears an analysis prepared by the Bureau of Legal Medicine and Legislation of the American Medical Association of the proposed Wagner-Murray-Dingell bill for broadening the American social security program. The Board of Trustees and the newly created Council on Medical Service and Public Relations of the American Medical Association will, no doubt give careful consideration in the near future to the policy of the Association regarding this specific measure. Arrangements will probably be considered for representation at hearings before the appropriate committees of the Senate and the House. Announcements made by the chairmen of the committees of the Senate and of the House in charge of the bill indicate that this legislation is not likely to come for consideration previously to the next session of Congress. In the meantime physicians should inform themselves concerning its genesis and its objectives.

In its evolution the Wagner-Murray-Dingell bill stems from the National Health Conference of 1937, the Wagner bill which followed that conference, and the report of the National Resources Planning Board. Essentially in its medical aspects it is a compulsory sickness insurance bill and an attempt to translate the proposals of the Social Security Board into a technic of action. Inquiry of reliable sources in Washington indicates the probability that the actual designers and authors of the bill included I. S. Falk, director of the Bureau of Research and Statistics of the Social Security Board of the Federal Security Administration, Mr. Wilbur J. Cohen, technical adviser to the Social Security Board, and Senator Wagner's secretary, Mr. Philip Levy. A statement issued by William Green, president of the American Federation of Labor, says "The measure, which is the most comprehensive attempt yet made to establish postwar security in this country, is the fruit of a five year study by experts on the staff of the American Federation of Labor, which will give the proposed program full sponsorship and support."

Inquiry also reveals that, as far as can be determined, representatives of the medical profession, either within or without the government, were not consulted in the development of the medical provisions. Evidence of this failure to consult the medical profession appears in the language of the proposed bill, since it speaks twice of a "spell of sickness." The word "spell," thus employed, does not appear in English dictionaries except as a colloquialism in Webster, and the term is seldom, if ever, used by any one educated in medicine.

A study of the analysis by the Bureau of Legal Medicine and Legislation will reveal to the medical reader the terms of the proposal. Speaking bluntly, however, the measure apparently attempts to avoid the innumerable difficulties involved in developing a government controlled medical service by making the Surgeon General of the Public Health Service, whoever he might be, a virtual "gauleiter" of American medicine. Indeed, it is doubtful if even Nazidom confers on its "gauleiter" the powers which this measure would confer on the Surgeon General of the U. S. Public Health Service. Here are some quotes:

The Surgeon General of the Public Health Service is hereby authorized and directed to take all necessary and practical steps to arrange for the availability of the benefits provided under this title.

The Surgeon General is hereby authorized to negotiate and periodically to renegotiate agreements or cooperative working arrangements with appropriate agencies of the United States, or of any state or political subdivisions thereof, and with other appropriate public agencies, and with private agencies or institutions, and with private persons or groups of persons, to utilize their services and facilities and to pay fair, reasonable and equitable compensation for such services or facilities.

There is hereby established a National Advisory Medical and Hospital Council to consist of the Surgeon General as Chairman and sixteen members to be appointed by the Surgeon General.

The Surgeon General shall publish and otherwise make known in each area to individuals entitled to benefit under this title the names of general practitioners who have agreed to furnish services.

Services which shall be deemed to be specialist services shall be those so designated by the Surgeon General, and the practitioners from among those included in paragraph 1 above who shall be qualified as specialists and entitled to the compensation provided for specialists shall be those so designated by him as qualify to furnish such specialist services.

Payments from the Trust Fund to general practitioners shall be made on the basis of fees for services rendered to individuals entitled to benefits, according to a fee schedule approved by the Surgeon General.

The Surgeon General may prescribe maximum limits to the number of potential beneficiaries for whom a practitioner may undertake to furnish general medical benefit.

The Surgeon General is hereby authorized to establish necessary and sufficient hearing and appeal bodies.

The Surgeon General shall publish a list of institutions found by him to be participating hospitals. Inclusion of an institution upon such list shall, unless and until withdrawn by him, be conclusive.

The Surgeon General and the Social Security Board may determine for any calendar year that each individual entitled to general medical benefit may be required by the physician furnishing such benefit to pay a fee in respect to the first service or with respect to each service a spell of sickness or course of treatment.

The Surgeon General and the Social Security Board jointly shall have the duty of studying and making recommendations as to the most effective methods of providing dental, nursing and other needed benefits.

The Surgeon General, after consultation with the Social Security Board and with the approval of the Federal Security Administrator, shall make and publish such rules and regulations necessary to the efficient administration.

The term 'laboratory benefit' means such necessary laboratory or related services, supplies or commodities as the Surgeon General may determine including chemical bacteriological, pathological diagnostic and therapeutic x-ray, and related laboratory services, physiotherapy, special appliances prescribed by a physician and eye glasses prescribed by a physician or other legally qualified practitioner.

With respect to inclusion in the list of participating hospitals the Surgeon General may accredit a hospital for limited varieties of cases and may accredit an institution for the care of the chronic sick.

This list is not all inclusive. There are many other points which space simply does not permit to be included in an editorial.

In offering the bill, its proponents emphasize that it provides for free choice of doctors, free choice of a doctor means, of course free choice of doctors willing to engage in this type of work.

The proposed measure has already been discussed editorially by such newspapers as the *Washington Star* and the *Chicago Daily News*, both of which pointed out that its passage would accumulate, at least for the present, deductions from many workers' wages of 20 per cent for income tax, 10 to 25 per cent for war bonds, 12 per cent for social security and such other special deductions as are already made in many individual plants. According to these figures there would be a minimum deduction of 42 per cent and a maximum deduction of 57 per cent of the worker's wages. The *Chicago Daily News* said:

We suspect that zeal for social security in the sweet by and by will have a hard time surmounting the shriveled paycheck already here with the future shrinkage now plainly in sight.

DOCTORS IN CONGRESS

In the Seventy-Eighth Congress of the United States there are seven physicians. They include:

Fred J. Douglas (R.), Utica, N. Y.
Ivor D. Fenton (R.), Mahanoy City, Pa.
Walter H. Judd (R.), Minneapolis
Joseph L. Pfeifer (D.), Brooklyn
Frederick C. Smith (R.), Marion, Ohio
Grant Furlong (D.), Donora, Pa.
Arthur L. Miller (R.), Kimball, Neb.

By the very nature of things, a physician in the Congress should be able to present to the membership of that august body the scientific point of view that is lacking from the education of most of the members, the majority of whom are lawyers. Indeed, with seven physicians holding membership one might anticipate that there would not be any difficulty in getting the medical evidence clearly before the legislators. Nevertheless it would not seem, if we are to believe Dr.

Walter H. Judd of Minneapolis, that any such possibility prevails. In a recent communication to *Minnesota Medicine* (June 1943) Congressman Judd says:

There are now seven of us doctors in Congress, by the way.

All of us got together, a while back, in the hope of fostering some sort of over-all scheme to take care of the medical situation. We hoped at least, to be on the inside so as to survey the situation in the hospitals, in the Army and the Navy and Public Health Service and make an over-all plan. But we didn't get anywhere.

The Public Health Service was interested but the Army and nothing doing and the Navy was even more reluctant. Each group wants the men and the power and neither will give way to the others. It is the same with many government agencies in Washington.

In fact I am convinced that what we need most in Washington is more doctors in government and above all, more of the kind of mental habits that good doctors must have.

In his statement to the Minnesota State Medical Association Congressman Judd also urged that the medical profession accept responsibility for leadership in medicine in the postwar period. "Certainly," he said, "neither you nor I want the professional philanthropists spinning out the alterations and calling the turn, though that is just exactly what will happen unless we take it over." He felt that medicine might well take the middle course between the "Old Guard," which says that things must stay as they are, and "the radical section that wants to scrap the entire system and start over." Congressman Judd also felt apparently that it was difficult for Congress or the Senate to obtain information concerning medicine. An investigation of the records in the headquarters office of the American Medical Association indicates that heads of practically every governmental agency call at frequent intervals on the American Medical Association in their desire for accurate information regarding medical proposals. The Bureau of Legal Medicine and Legislation and the state medical societies regularly send to their representative in the Congress information regarding pending medical and health legislation. Unfortunately, some members of Congress studiously avoid any attempt to obtain consultation or information, as is indicated elsewhere in this issue in an editorial discussion of the Wagner-Murray-Dingell bill.

The contacts of American medicine in municipal, state and federal government are surrounded in these times with hazardous possibilities. Motivations are constantly questioned. Indeed, in his presidential address to the Minnesota State Medical Association Dr. Stephen H. Baxter pointed out that the activities of the Minnesota State Medical Association in relation to state legislation had recently been questioned by the state senate and "that a resolution was presented to the Senate Committee calling for an investigation of the activities of the representatives of our Association at the Capitol. This resolution was not adopted, but it was widely publicized, and the very fact of its introduction created in the minds of many people, impressions unfavorable to the Association."

UNITED NATIONS CONFERENCE ON FOOD AND AGRICULTURE

Last month delegates from practically all of the governments opposed to the Axis powers, including representatives from both free and occupied countries, met at Hot Springs, Va. The purpose of the meeting was to further the development of national and international nutrition policy. The meeting was entitled the United Nations Conference on Food and Agriculture. The features of that conference which are of particular interest to the medical profession are summarized in the report of Section I dealing with food and the resolutions adopted by that section and by the recommendations of Section IV embodying the program for continuing and extending the work of the conference, the latter being the overall declaration regarding future procedure in international collaboration.

The most important basic assumptions were matters of general agreement. The evidence for association between faulty diet and ill health is conclusive. Ill health results from insufficient quality or variety of food as well as from deficient quantity. Widespread impairment of human efficiency as well as specific diseases result from malnutrition. There are also special population groups which are particularly vulnerable to the effects of faulty diet—pregnant and nursing women, infants, preschool and school children and adolescents. Certain common diseases such as tuberculosis are directly associated with lowered resistance caused by malnutrition—this in addition to the specific food deficiency diseases. There has never been enough food in the world for the people of the world to eat. The primary factor responsible for this condition is poverty. Improved economic conditions invariably lead to better nutrition, the better health thus effected prepares the way for ameliorating the economic lot.

It is useless, the report points out, to produce more food unless the markets are able to absorb it. It is necessary therefore not only to provide vastly increased quantities of food and in suitable variety but to make foodstuffs available to larger numbers of people by all the various means available. Thus an expansion of a whole world economy is necessary in order to furnish the purchasing power to make the wider distribution of foodstuffs feasible. In order to avoid the charge that this program is purely idealistic without the possibility of practical application, the report specifically recognizes that different peoples have varying tastes and food resources and that innumerable combinations of individual foods may be devised by which the necessary nutrients in suitable quantities can be provided largely within the resources of the local area. This may be facilitated by tables which permit the recommended allowances of specific food substances to be readily

translated into foods in common local use. By this means the value of diets commonly consumed by any population group can be compared with such standards and deficiencies readily estimated.

Recognition of the problem culminated in a series of resolutions adopted by the conference. International as well as national action is necessary if food policies based on human requirements are to be adopted throughout the world within a reasonable period of time. The problems of inadequate food consumption and malnutrition are urgent and have been profoundly aggravated by the war. Recognizing the impossibility of immediate or early solution of the nutrition problem, the conference nevertheless recommended that governments adopt as the ultimate goal of their policy dietary standards and allowances based on scientific assessment of the amount and quality of food which promote health and that they distinguish clearly between these standards and the more immediate consumption goals. Among the steps adopted to implement this policy, the conference recommended the immediate establishment of an appropriate "United Nations Food and Agricultural Organization," one of the functions of which would be to institute studies and investigations into food production and consumption throughout the world and to advise and assist governments in carrying out the recommendations of the conference. Further, the several governments represented at the conference should immediately undertake to ascertain the prevalence of specific deficiency diseases among their people, dealing with them by suitable dietary and therapeutic measures, and take appropriate steps to prevent their recurrence. Especially important is the early provision of extra foods for those especially vulnerable elements of the population. Wide public education is necessary. National nutrition organizations in those states in which they do not now exist should be formed. These several national organizations should exchange information and experience and provide mutual assistance both directly when desirable and through the medium of the proposed United Nations Food and Agricultural Organization by the submission of periodic reports. The setting up of regional branches of the United Nations organization in various parts of the world is recommended.

The sound evaluation of basic facts, the common sense differentiation between ultimate goals and immediate or early practicable measures, the setting up of what promises to be a workable international organization and the apparent general agreement of all delegates offers great promise for the gradual improvement of standards of nutrition throughout the world. If support by the medical profession of any sound program to improve general nutrition is a foregone conclusion

Current Comment

QUININE

Malaria as THE JOURNAL has frequently emphasized, is probably medical war problem No. 1. The provision of quinine, totaquine, atabrine and other remedies for malaria has been one of the most difficult aspects of the procurement situation. THE JOURNAL has already called attention to efforts that are being made to conserve all available quinine for military purposes, to collect every gram of quinine that could be collected from even retail drug stores and household medicine cabinets and to develop sources of quinine among our South American neighbors. Into this situation suddenly has been tossed a circular issued by the Cinchona Products Institute, Inc., of New York which represents largely the Dutch interests that controlled cinchona products in Java. This circular mailed widespread throughout the nation and offered for display in schools, clinics, drugstores and any other public place urges the American public to get quinine for the treatment of malaria, perhaps self diagnosed. It states that "Quinine comes from the bark of the cinchona tree, a native of South America but best grown in Java." True, cinchona was apparently best grown in Java previous to Pearl Harbor, but the cinchona grown in Java means nothing now to the campaign against malaria among the forces of the United Nations. Physicians have been requested not to prescribe quinine even for malaria in this country if they can substitute totaquine or other available remedies. Druggists have been requested indeed forbidden to fill prescriptions for quinine for any other purpose than the treatment of malaria. Obviously the Cinchona Products Institute, Inc. has rendered no service in the war situation by the kind of publicity in which it has indulged, rather, its effort has been a disservice. Perhaps any intelligent reader may hazard a guess as to the motivation which stimulated the production of this circular at this time.

EPIDEMIC NAUSEA AND VOMITING

Recently various communities—usually localized—have been affected with a peculiar condition characterized by acute attacks of severe vomiting, generally lasting a few hours only, often involving all the members of a family or group, frequently not associated with other symptoms and with a completely benign outcome. This comparatively trivial disorder, according to Bradley¹ has become much more common of late in England. Although the disease is of minor significance clinically and economically, it may give rise to considerable administrative uncertainty. Those who are unfamiliar with the clinical and epidemiologic picture may be led to suspect food poisoning and dysentery and be stampeded into ineffectual and wasteful action. It is unusual, Bradley points out, for patients affected with this disorder to call their doctors, since most of them begin to feel better within a few hours. Vomiting is the most characteristic sign, and in young people it tends to be projectile and of great urgency. Usually nausea

is present with the vomiting but more characteristically precedes it for a few hours and in some cases persists unaccompanied by emesis. Vertigo, aches and diarrhea are of less frequent occurrence. By simple questioning a number of family outbreaks have been brought to light. Community outbreaks in girls' and boys' boarding schools have occurred and have received some study. Epidemiologic reports as far as available strengthen the impression that the disease is communicable and that the port of entry is the upper respiratory passages. Incubation periods are probably within the range of two to seven days but have not been determined accurately. The possibility that this condition may become more severe cannot be entirely ignored.

TRANSPLACENTAL FILTRATION OF VITAMIN C

The concentration of vitamin C is higher in fetal blood than in the maternal circulation.¹ Earlier clinicians interpreted this as evidence of the ability of the fetus to synthesize vitamin C. Manahan and Eastman,² however, believe that the difference is due to a one way selective filtration of vitamin C through the placenta. This filtration theory has recently been subjected to detailed clinical study by McDevitt and her co-workers³ of Bunne Bay Cottage Hospital, Norris Point, Newfoundland, on patients encountered in the course of a nutritional survey. There were careful dietary histories before and after delivery. Repeated vitamin C titrations were made of maternal plasmas before delivery and immediately after childbirth, with control determinations of the vitamin C content of blood collected from the umbilical stump. The patients included those on adequate diets as well as several patients with definite vitamin C deficiency. Some of the patients with deficiency had been given vitamin C therapy. The average of all cases (including deficiency cases) was 0.43 mg. of vitamin C per hundred cubic centimeters in maternal plasma before delivery, with an average of 0.53 mg. per hundred cubic centimeters a few hours after delivery. The average cord blood contained 1.24 mg. of vitamin C per hundred cubic centimeters, an amount approaching the zone of vitamin C saturation. The fetal blood titer was as high as 1.90 mg. in patients given antepartum vitamin C saturation tests and as low as 0.33 mg. in certain patients who suffered from prolonged deprivation of vitamin C (maternal plasma titer 0.06 mg. per hundred cubic centimeters). The Newfoundland clinicians emphasize the latter result, since it suggests that latent scurvy of the newborn is a clinical possibility. In all cases in which the maternal blood titer was above 0.33 mg., however, the fetal blood titer was near the vitamin C saturation level (1.30 mg. per hundred cubic centimeters). The physicochemical or cytologic factors responsible for this one way selective placental filtration have not yet been determined. The possibility of a similar selective filtration of other vitamins or of other nutritional factors has also not yet been tested.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

DAILY PROGRAM FOR CONVALESCENTS

Under a new program at the Station Hospital at Blackland Army Air Field, Waco, Texas, designed by the medical department of the Army Air Forces (THE JOURNAL, March 27, p. 1096), the soldier-patient follows a daily educational and physical training program which supplements his military knowledge, builds up his strength, and combats boredom, while he awaits recovery. Calisthenics, outdoor and indoor games, classes, training films, review of current news events, prescribed reading and regular work details are given the patients on the road to recovery. All patients are grouped into four classes according to their stage of recovery and each class follows its specific program. Each patient also receives an individual program based on his case.

The original assignment and the speed of progression through the classes are determined for each individual by the doctor in charge of the ward in which he is a patient in consultation with the officer in charge of the reconditioning program at the hospital. By following this plan the exercises are prescribed on a scale graded to approach closely, but never exceed, the individual's tolerance. The program has proved to be popular with patients. A typical daily schedule in addition to the work details is as follows: a five minute review of current news, a thirty minute lecture on a selected subject, a showing of one or more suitable training or recreational films, a minimum of one-half hour prescribed reading and a suitable period of physical exercise or drill.

A weekly schedule of the five daily courses given Monday through Friday is carried out. Four week schedules are prepared in advance suitable for each patient's first, second, third and fourth week of convalescence. The physical exercises are divided into three groups: those suitable for bed patients, ones suitable for ambulatory patients and a program for late convalescents.

During the first week of convalescence the patient is shown films or given lectures on the identification of Japanese aircraft, military courtesy and customs, personal hygiene, individual protection and the identification of U S aircraft. The second week he hears and sees training material on the identification of German aircraft, safeguarding military information, care of clothing and equipment, friend or foe, first aid, the care and use of the gas mask and incendiary bombs. The identification of Italian aircraft, interior guard duty, detection of booby traps, proper treatment of gas casualties and jungle warfare are topics taught during the third week. In the last week of the program the soldier is instructed in forced landings, weather, attack aviation, camouflage, map reading, arctic warfare and the motor vehicle driver.

The Army Air Forces Hospital program at Blackland Army Air Field was placed in operation by Lieut. Daniel D. Blum of the Medical Administrative Corps of Jersey City, N. J.

FELLOWS IN AVIATION MEDICINE

The new constitution and by-laws of the Aero Medical Association of the United States provide for the nomination of the initial group of ten fellows and for the election of fifteen additional fellows which shall comprise the first group of fellows of the association. The by-laws adopted last September further provide that all subsequent elections to the grade of fellow shall be by the Group of Fellows, which shall be by selection only from those who have made outstanding contributions to

aviation medicine, of whom not more than ten shall be elected in any one year at a meeting of the Group of Fellows just prior or during the annual session of the association.

The following comprise the first group of twenty-five fellows to be elected, together with their present addresses. Colonel Armstrong, Captain Poppen, and Captain Wright are at present outside continental United States and for military reasons their addresses are not given. Dr. Ralph N. Greene, Coral Gables, Fla., was elected a fellow posthumously.

FELLOWS IN AVIATION MEDICINE

Col. Eldridge S. Adams, M. C., Bowman Field, Louisville, Ky.
Capt. J. C. Adams (MC), U. S. N., flight surgeon in charge of Division of Aviation Medicine, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.
Col. Harry G. Armstrong, M. C., U. S. Army
Dr. Louis H. Bauer, Hempstead, N. Y.
Col. Otis O. Benson Jr., M. C., Materiel Center, Wright Field, Dayton, Ohio
Dr. Harold R. Bohlman, Baltimore
Dr. D. S. Brachman, Detroit
Dr. James C. Braswell, Tulsa, Okla.
Comdr. L. D. Carson, (MC), U. S. N., Navy Department, Washington, D. C.
Dr. J. C. Cole, New Orleans
Major Herbert F. Fenwick, M. C., Army Air Forces, Miami, Fla.
Dr. Charles H. Gowan, Glendale, Calif.
Brig. Gen. David N. W. Grant, Air Surgeon, War Department, Headquarters Army Air Forces, Washington, D. C.
Dr. A. J. Herbolzheimer, Civil Aeronautics Administration, Washington, D. C.
Major Bernard L. Jarnian, M. C., U. S. Army, Washington, D. C.
* Comdr. Eric Liljencrantz (MC), U. S. N., Washington, D. C.
* Major R. F. Longacre, M. C., Los Angeles
Lieut. Col. W. Randolph Lovelace II, M. C., Materiel Center, Wright Field, Dayton, Ohio
Dr. Albert M. Mitchell, Terre Haute, Ind.
Capt. John R. Poppen (MC), U. S. N.
Brig. Gen. E. G. Remartz, A. U. S., Commandant, School of Aviation Medicine, Randolph Field, Texas
Col. R. Keith Simpson, M. C., Randolph Field, Texas
Dr. John A. Tammisla, Omaha
Col. A. D. Tuttle (Ret.), Chicago
Capt. Herbert B. Wright, M. C., U. S. Army
* Deceased

DR. STRECKER NAMED SPECIAL CONSULTANT IN PSYCHIATRY

Dr. Edward A. Strecker of Philadelphia, president of the American Psychiatric Association, has been named special consultant to the Secretary of War for the Air Forces of the United States Army, according to an announcement by the American Psychiatric Association. He will be on call at all times by the War Department. A month ago Dr. Strecker was named consultant in psychiatry to the Surgeon General of the U. S. Navy. He recently established an intensive training school for naval medical officers in Philadelphia. All the medical and hospital facilities throughout the city are cooperating in this program, three months in length. In the first world war he was division neuropsychiatrist for the Twenty-Fifth Division in France. Dr. Strecker is professor and head of the department of psychiatry at the University of Pennsylvania Graduate School in Philadelphia and the Medical School of the same university. He is chief of service and consultant at the Institute for Mental Hygiene of the Pennsylvania Hospital, consultant for Bryn Mawr College and the United States Veteran's Bureau, and staff neurologist for the Philadelphia and Germantown hospitals.

RETURNED FROM GUADALCANAL

In order to give Medical Department officers the benefit of his experience in the South Pacific theater of operations, Lieut. Col. A. H. Thompson, M. C., has become a member of the faculty at the Medical Field Service School, Carlisle Barracks, Pennsylvania. Lieutenant Colonel Thompson had been assistant to the department surgeon in Hawaii before being assigned surgeon of the 25th Division shortly before the attack on Pearl Harbor. The division was ordered to Guadalcanal in November 1942. He tells of the battle of Grassy Knoll in December and of other battles farther to the west. Improvisation was necessary in order to get wounded men back to medical stations where they could be given definitive care. Jungle growth, steep hills and marshy ravines made hand carrying of litters difficult. Some Navy Stokes litters were used together with a pulley arrangement so that wounded men could be brought down a steep hill by means of a cable. Litter bearers in one sector came on three wounded men, one of whom weighed 255 pounds. In shifts twelve litter bearers struggled eight hours to carry that patient through the jungle back to a medical station. In one section the wounded were brought out by water on rafts and boats captured from the Japanese. Speaking of the hospital, Lieutenant Colonel Thompson told of operating lights made of tin cans the inside being painted with white enamel to give better reflection. The serious casualties later were evacuated from Guadalcanal to New Caledonia. Lieutenant Colonel Thompson said that the natural aptitude of the natives of Guadalcanal made them excellent litter bearers; that Japanese prisoners were grateful for their medical care and that practically all of them were suffering from malnutrition, starvation, malnutrition and beriberi. Lieutenant Colonel Thompson is a graduate of the University of Pittsburgh Medical School and of the Army Medical School in the class of 1938-1939.

ARMY AIR FORCES RECEIVE AWARD

The achievement of the U. S. Army Air Forces in training 95 out of every 100 pilots without injury of any kind has been recognized by the National Safety Council which has bestowed its special wartime award "For Distinguished Service to Safety on the Army Air Forces."

Col. John Stulwell, president of the Council, said in announcing the award that a study of the figures of the Flight Control Command shows a downward trend in the rate of all army airplane accidents as well as of fatal accidents during the eleven month period from July 1942 to June 1, 1943. Despite the great increase demanded by the war in both the number of hours and in the miles flown in training schools throughout the country, more than 95 per cent of Army Air Forces pilots and student pilots are completing their training period with no personal injury of any kind. Moreover, figures show there has been only one fatal accident for every 1,750,000 miles flown in recent months. This is a remarkable achievement in accident prevention. The citation which Col. Stulwell will present in Washington to General H. H. Arnold reads in part as follows:

The National Safety Council believes that the ceaseless efforts of the Flight Control Command to prevent accidents constitute a spectacular fulfillment of America's traditional insistence that the triumphs of war be never achieved at the expense of the ideals of peace.

DISEASE PREVENTION IN NORTH AFRICA

The War Department announced on June 2 that American soldiers in North Africa are almost free of infectious and contagious diseases. Contributing to this result have been the medical department and the engineers and quartermaster corps. One of the most effective forces against the hordes of mosquitoes the War Department said has been a new lotion which the soldier rubs on the exposed parts of his body. A single application repels mosquitoes for at least four hundred minutes. Flies and other insects have been fought with a bomblike device which the soldier sets off with a trigger. It contains a spray that kills all flies and insects in an ordinary sized room and yet is harmless to human beings. The elimination of lice is

accomplished by a new powder which is sprinkled on clothes. The elaborate apparatus for delousing used in the last war is no longer required. However, as a general rule American troops in Africa have been free of these pests.

MEDICAL REPLACEMENT TRAINING CENTER

Night problems, bivouac maneuvers and obstacle courses are regular features of the training at the Medical Replacement Training Center at Camp Robinson, Arkansas, all aimed to toughen medical soldiers to enable them to carry on their difficult tasks wherever assigned. From 5:45 a. m. until 5:45 p. m., six days a week, medical trainees are impressed with the importance of their work and with the technical knowledge necessary to carry it out. Brig. Gen. James E. Baylis is in command; the executive officer is Col. Frank S. Matlack; the Plans and Training officer is Col. Robert E. Peyton. The commanders of the medical training regiments and battalions are officers of the medical corps.

DIRECTOR OF NURSING SERVICE IN NORTH AFRICA PROMOTED

The War Department announced on May 20 the promotion of First Lieut. Bernice M. Wilbur, Army Nurse Corps, director of the Nursing Service for the North Africa Theater of Operations, to lieutenant colonel. Colonel Wilbur has departed for her post after a short leave. She returned to the United States with Lieut. Gen. Lesley J. McNair, commanding general, Army Ground Forces, who was wounded while on an inspection trip in North Africa. Colonel Wilbur has been directing the nursing service in the North African theater since last December. Her home is in Boston where she graduated from the New England Deaconess Hospital.

VOLUNTARY WAR HOSPITAL SERVICES, INC.

Voluntary War Hospital Services, San Francisco, a nonprofit, nonsectarian organization recently incorporated, will continue the work carried on by Mrs. Janet Lindsley since shortly after Pearl Harbor to give wounded men entertainment, to assist in their rehabilitation and to find employment for those permanently injured or disabled. Voluntary War Hospital Services has already furnished a number of solariums at the base hospitals. Convalescents have also received thousands of kits, hundreds of slippers and numerous radios which have been donated.

DR. OSBORNE MISSING

The War Department has informed Mrs. Mildred Osborne of Vicksburg, Mich., that her husband, Capt. Charles E. Osborne, is still reported officially as missing in action. A year ago the War Department reported Dr. Osborne as missing. Captain Osborne was stationed at Base Hospital No. 1 on Bataan at the time the Japanese took that area.

LECTURE ON TROPICAL DISEASES

Dr. Marcos Fernan-Nunez, professor of pathology, Marquette University Medical School, Milwaukee, addressed the combined medical staffs of Army General Hospital No. 17 (Harper Unit) and the Post General Hospital of Camp McCoy, Wisconsin, April 5, on "War Problems in Tropical Diseases."

FLIGHT SURGEONS' ASSISTANTS

A course of instruction to qualify enlisted men as assistants to flight surgeons began at the School of Aviation Medicine in Texas on March 29 and continued for six weeks. About eighty-one sergeants, corporals, technicians of various grades and privates were enrolled in the class.

CIVILIAN DEFENSE

RULES FOR AFFILIATED
HOSPITAL UNITS

The Office of Civilian Defense, Washington, D C, on June 8 issued Circular Medical Series No 31, which follows (slightly edited)

One hundred and ninety one hospitals and medical schools have been invited by the Surgeon General of the U S Public Health Service to organize affiliated hospital units of the Emergency Medical Service of the U S Office of Civilian Defense. The invitation was extended to so large a number of civilian hospitals because each unit will be called on for service only in a war emergency affecting its own region. Units will be activated only in event of a grave military disaster affecting the civilian population or military personnel in the area in which the parent hospital is located. Activation of a unit will take place only on recommendation of the state chief of Emergency Medical Service and the Office of Civilian Defense regional medical officer, subject to certain limitations imposed by the Surgeon General and the chief medical officer of the Office of Civilian Defense and by agreements with the invited hospitals.

The rules governing activation of affiliated units are as follows:

1 Members of the staffs of affiliated units are commissioned in the inactive reserve of the U S Public Health Service, generally with the rank of passed assistant surgeon, surgeon or senior surgeon (equivalent respectively to army ranks of captain, major or lieutenant colonel). They will remain on inactive status for the duration of the war unless urgent need for their services should arise in their region because of an air raid or other grave wartime disaster. When activated under such circumstances, these officers will receive the pay and allowances of officers of equivalent grades in the armed forces.

2 The two specific purposes for which a unit may be activated are:

(a) For duty in an emergency base hospital to which civilian casualties and other hospitalized patients must be transferred because a community is under enemy attack and one or more of its hospitals must be evacuated.

(b) For temporary duty to assist the armed forces at the time of an extraordinary military emergency. The period of emergency assistance is expected to be of short duration and will last only until the Surgeon General of the Army can send in additional medical officers or until he can distribute the excessive load of sick and wounded to military hospitals in other parts of the country. Affiliated units are organized primarily for civilian protection and are not to be used to staff military hospitals as they expand to meet increasing medical requirements of the Army.

3 Affiliated units organized by the Medical Division of the Office of Civilian Defense as part of the Emergency Medical Service of their states will be expected to provide aid only in their own or neighboring states. Their members will not be detached for duty in other parts of the country, nor will they be activated for any other duty except those listed in paragraph 2.

4 A unit organized from the staff of a teaching hospital of a medical school will not be called unless the hospital itself must be evacuated or unless there is no unit from a nonteaching hospital to meet the emergency need.

5 The period of obligation for service will cease at the termination of the present national emergency, the Surgeon General will accept resignations of members of units six months after cessation of hostilities.

6 A commission in the inactive reserve of the U S Public Health Service does not prevent a member of an affiliated unit from entering the armed forces, resignation will be accepted for this purpose.

7 Members of affiliated units may wear the authorized lapel buttons which indicate that they have enlisted for emergency service. They are not to wear the uniform until called to active service and need not purchase a uniform unless the possibility of active service is imminent. Uniforms will not be required for brief periods of active service.

The organization of such affiliated units has received approval of the Board of Trustees of the American Medical Association, and the directing board of the Procurement and Assignment Service has authorized "essential" physicians to accept positions in affiliated units.

HOW TO PROTECT YOURSELF
AGAINST WAR GAS

The Office of Civilian Defense, Washington, D C, issued on May 15 Operations Letter No 128, which supersedes Operations Letter No 46 concerning protection against war gas.

1 Stay indoors. A tightly closed room affords protection against war gas. All windows and doors should be tightly shut, and blankets (to be soaked with water) or cardboard should be kept in readiness to cover and seal shattered windows. Choose a room on an upper floor if possible, most war gases are heavier than air, although they may be carried up with air currents.

2 If caught outdoors in a gas attack, get out of the area at once. Look down and shield your eyes with your arm. Do not worry about any brief vapor exposure to which you may be subjected. The danger from this source is not great.

3 Prompt action will avoid serious effects. If you know or suspect that you have gotten any of the gas on your person or clothing, do not go hunting for a casualty station or gas cleaning station and expect some one else to help you. Knock on the first door you come to, and take whatever steps are necessary. Self aid is the quickest and safest way.

4 This is what you should do. This routine should be memorized so it will be done automatically in an emergency:

(a) Remove shoes and outer clothing and drop them outside the house, in a covered can if available. Do not touch this clothing again except with sticks or gas proof gloves. Do not cling to false modesty. To enter a house with contaminated clothing endangers everyone in it.

(b) Get to a bathroom, kitchen or laundry room as fast as possible.

(c) If your eyes have been exposed to liquid gas or spray, flush them immediately. Plain water out of a faucet, shower head, canteen or douche bag will do, but a lukewarm dilute solution of sodium bicarbonate (heaping tablespoon in a quart of water) is even better, if it is handy. Let any one nearby help you.

(d) If drops of liquid blister gas have splashed the skin, you can prevent serious burns by adequate cleansing. Promptly blot up the liquid with pieces of cleansing tissue, cloth or a handkerchief, which should be disposed of carefully in order that it cannot contaminate any one else. Then sponge the skin briskly with laundry bleach containing sodium hypochlorite, if it is at hand, and rinse off under the shower or in a tub. A thorough bath with a vigorous lathering is the final step, which should never be omitted. Dry the skin by patting. Do not rub. Dress in whatever clean clothing you can get. If blisters develop, you should seek medical advice.

(e) If your nose and throat feel irritated, snuff and gargle with a dilute solution of sodium bicarbonate. If your chest feels heavy and oppressed, if you have any trouble breathing or if smoking becomes distasteful, lie down immediately and stay perfectly still until you can be taken to a doctor. Do this even if you feel fine otherwise.

5 Remember. Cleanse yourself quickly and calmly. Follow the instructions of your air raid warden.

RECREATION IN WARTIME

With the cooperation of the Office of Defense Health and Welfare Services, the Office of Civilian Defense has published a pamphlet for the use of local defense council committees in the field of civilian war services setting forth the particular duties and functions of the recreation committee of the defense council and suggesting a program of recreation. This committee may help carry out in its particular area.

WAR FOOD ADMINISTRATION—FOOD DISTRIBUTION ADMINISTRATION

RATIONING AND EXPERIMENTAL LABORATORIES

The question of the procedure for obtaining rationed foods for experimental purposes has been raised by a number of research institutions. In order to help those having difficulty in satisfying their needs, the following note has been prepared.

Amendment 18 to General Ration Order Number 5 issued April 24 1943 states that On and after May 1 1943 any use of a rationed food for experimental educational testing or demonstration purposes is an industrial and not an institutional use. This amendment lists experimental laboratories as industrial users and therefore requires them to proceed as directed under the institutional and industrial users sections of the various ration orders.

An industrial user (laboratory) registers either in person or by mail with the local board serving the area in which his principal office is located and receives an allotment to enable him to obtain and use foods covered by food rationing orders.

An application for the opening of a new establishment (laboratory) or original application to obtain rationed commodities must be made on OPA form R-315. Such application should be submitted to the local war price and rationing board which serves the area in which the establishment (laboratory) or its principal business office is or will be located. The local board will forward the application with its recommendation and all supporting data to Washington for appropriate action.

An application by an industrial user (laboratory) for allotment of a specific rationed food must be made in the following manner:

Sugar—If the applicant (laboratory) used sugar in 1941 his allotment will be based on actual usage during that year. He must register on OPA form R-310 and apply for his allotment on R-314. The local board shall take appropriate action.

If the applicant did not use sugar in 1941, his allotment will be granted by the local board in accordance with the ruling received from Washington, where the petition shall be sent by the local board.

Coffee—A laboratory which uses coffee for experimental purposes is considered a class A industrial user of coffee and a person who uses roasted coffee in the preparation of a beverage which he does not serve. He must apply to his local War Price and Rationing Board, which shall determine his monthly allotments.

Processed Foods—The applicant shall register on OPA form R-1308 and include a record of his historical use of processed food on which subsequent allotments will be based.

Meat, Cheese, Butter and Edible Fats and Oils—The applicant shall register as an industrial user on OPA form R-1605 and include a record of his historical use of foods rationed under ration order 16 and his inventory of such rationed foods as of March 28, 1943. Allotments will be issued accordingly.

Sections 140781 to 140795 of ration order 3 cover the industrial use of sugar. Sections 14071015 to 140710175 of ration order 12 cover the industrial use of coffee. Article VI of ration order 13 and amendment 10 to that order cover the industrial use of processed foods. Article VII of ration order 16 covers the industrial use of meats, cheese, butter and the edible fats and oils.

Additional information as to the procedure for obtaining rationed foods for experimental purposes as well as copies of the various rationing orders, amendments and necessary forms may be obtained from local war price and rationing boards.

MISCELLANEOUS

NEW WARTIME NUTRITION CHART

This is the new official wartime nutrition food chart of the national wartime nutrition program. The seven food groups and the slogan "Eat the Basic 7 Every Day" have been adapted to the current food situation. Copies of this chart in six colors will be available about the middle of June.

A folder entitled "The National Wartime Nutrition Food Guide" which will explain the basic seven, will probably be ready for distribution the latter part of July. This folder gives practical suggestions for meeting wartime food shortages without sacrificing good nutrition.

Both the chart and the folder may be obtained without cost from the regional offices of the Food Distribution Administration. The charts will be of interest to both doctors and their patients and they will find the folder helpful in solving their wartime food problems.

The slogan "U S Needs Us Strong—Eat the Basic 7 Every Day" retains the best part of the former slogan "U S Needs Us Strong—Every Day Eat This Way" and stresses the basic seven food groups. The circular presentation of the seven food groups emphasizes the fact that all groups are important and avoids putting any one group ahead of the others.

The Nutrition Division of the Office of Defense Health and Welfare Services, Federal Security Agency, is now incorporated in the Department of Agriculture Food Distribution Administration as the Nutrition and Food Conservation Branch.

The state and local nutrition committees previously affiliated with the Nutrition Division will continue their work with the Nutrition and Food Conservation Branch. They will as in the past act as the integrating and coordinating agencies for the activities of all groups engaged in improving nutrition. The regional nutritionists with headquarters at the Food Distribu-

*For Health...eat some food
from each group...every day!*

**IN ADDITION TO THE BASIC 7 ..
EAT ANY OTHER FOODS YOU WANT**

New official wartime nutrition chart

tion Administration regional offices will continue to work with state and local nutrition committees

The program of the Nutrition and Food Conservation Branch includes

1 A nationwide educational program on all phases of good nutrition geared to the wartime food situation and including (a) efficient utilization of available foods, shown by food demonstrations, (b) conservation of the physical volume and nutritive value of food, from production point to table, and (c) food preservation program covering methods of home and community canning

2 Support of community nutrition programs such as school lunch programs

3 Guidance and assistance with in-plant feeding projects for industrial workers

4 Assistance to state and local health departments, in cooperation with the United States Public Health Service, in planning and carrying out public health nutrition programs which are closely tied in with the activities of the local nutrition committees

Location of regional offices of the Food Distribution Administration

REGION	ADDRESS	STATES INCLUDED
Northeast	150 Broadway, New York	Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Jersey, New Hampshire, New York, Pennsylvania, Rhode Island, Vermont, West Virginia

Montana, Wyoming Dr Ernest D Hitchcock, Great Falls, Mont., chairman
Colorado, Utah Dr James J Waring, Denver, chairman
New Mexico, Arizona Dr Carl Mulky, Albuquerque, chairman
Washington Dr John H O'Shea, Spokane, chairman
Idaho, Oregon Dr John H Fitzgibbon, Portland, chairman
Nevada, northern California Dr Ernest H Falconer, San Francisco, chairman
Southern California Dr Roy E Thomas, Los Angeles, chairman

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE ARRANGES COURSES

Ward walks, clinics, practical demonstrations, moving pictures and conferences for physicians in the armed services have been arranged by the Syracuse University College of Medicine, Syracuse, N Y, under the program of Wartime Graduate Medical Meetings. This instruction is available in Syracuse and vicinity and includes lectures at the College of Medicine and the teaching hospitals, and combinations of lectures with clinics, conferences and demonstrations. Teaching will be given in both afternoon and evening sessions. Teams of two or more teachers will hold sessions at camps or hospitals in nearby areas. Efforts will be made to provide instruction in those

fields for which requests are received. A tentative list of subjects and teachers has already been set up and includes the following

Allergy Ershler, Marty, Wiseman
Anatomy Armstrong
Bacteriology Chipman, Mueller
Broucheoesophagology Blaisdell, Rubenstein
Burns George Reed, Sutton
Chemotherapy Ernest Delmonico, Dooley, Ershler, Hughes, Laurie
Post, Silverman, Sutton
Dermatology Griggs
Ear, Nose and Throat Diseases Blaisdell, Brown, Cave, Kaufman
O'Connor, Moore, Rubenstein

ORGANIZATION SECTION

THE WAGNER-MURRAY-DINGELL SOCIAL SECURITY PLAN

An Analysis Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association,
June 16, 1943

Referred to generally as embodying an Americanized Beveridge plan but offered in Congress, according to Senator Wagner, simply as a basis for legislative study and consideration," legislation was introduced June 3 in the Senate by Senator Wagner, New York for himself and Senator Murray, Montana and in the House by Representative Dingell Michigan, proposing to create a United National Social Insurance System (S 1161, H R 2861). The Senate bill is pending in the Senate Committee on Finance and the House bill on the House Committee on Ways and Means.

The system proposed to be created will be financed in general from a trust fund established by a 6 per cent employee and a 6 per cent employer contribution on all wages and salaries, up to the first \$3000 a year, paid or received after Dec 31, 1943. Included in this proposed system will be a system of public employment offices increased old age and survivors insurance benefits temporary and permanent disability insurance benefits protection to individuals in the military service, increased unemployment insurance benefits under a federalized unemployment system, maternity benefits medical and hospitalization insurance benefits, a broadening of the basis of the existing social security program to embrace some 15,000,000 persons now excluded, such as farm workers and domestic servants, employees of nonprofit institutions, independent farmers, members of the professions and other self-employed individuals, and a unified public assistance program. There follows an analysis of those provisions of the ninety page bill that appear to be of particular concern to medicine.

DISABILITY BENEFITS PLUS MEDICAL CARE

The bill broadens the existing social security coverage by providing for the payment of cash permanent disability benefits to beneficiaries. In addition to such cash benefits, the Social Security Board through the Surgeon General of the Public Health Service will be authorized to make provision for furnishing medical, surgical, institutional, rehabilitation or other services to disabled individuals entitled to receive insurance benefits, if such services will aid in enabling such individuals to return to gainful work. Such services, it is contemplated, will be furnished 'by qualified practitioners and through governmental and nongovernmental hospitals and other institutions qualified to furnish such services'. In administering the provisions of this particular section of the bill, the Surgeon General and the Social Security Board will follow as far as applicable the procedure outlined by another section of the bill relating to medical, hospitalization and related benefits generally.

MEDICAL, HOSPITALIZATION AND RELATED BENEFITS IN GENERAL

Section 11 of the bill proposes to add a new title to the Social Security Act title IX, providing for a federal system of compulsory medical and hospitalization insurance for all persons covered under the old age and survivors insurance, and their dependents. Each insured worker and his dependent wife and children will be entitled to receive general medical special

medical laboratory and hospitalization benefits. In addition, the system is made elastic so that it may be enlarged in its coverage to admit other beneficiaries on a voluntary basis, such as self-employed individuals and employees of states and political subdivisions.

In order to appreciate the broad scope of this new title, consideration must initially be given to the meaning of the words and phrases used in it. The term 'general medical benefit' means services furnished by a legally qualified physician, including all necessary services such as can be furnished by a physician engaged in the general practice of medicine, at the office, home, hospital or elsewhere, including preventive, diagnostic and therapeutic treatment and care, and periodic physical examinations.

The term 'special medical benefit' means necessary services requiring special skill or experience, furnished at the office, home, hospital or elsewhere by a legally qualified physician who is a specialist with respect to the class of service furnished.

The term 'laboratory benefit' means such necessary laboratory or related services, supplies or commodities, not provided to a hospitalized patient and not included as a part of the general or special medical benefit as the Surgeon General of the United States Public Health Service may determine, including chemical, bacteriologic, pathologic, diagnostic and therapeutic x-ray and related laboratory services, physical therapy, special appliances prescribed by a physician and eye glasses prescribed by a physician 'or other legally qualified practitioner'.

The term 'hospitalization benefit' means (1) not less than \$3 and not more than \$6 for each day of hospitalization, not in excess of thirty days, which an individual has had in a period of hospitalization, (2) not less than \$1.50 and not more than \$4 for each day of hospitalization in excess of thirty in a period of hospitalization, and (3) not less than \$1.50 and not more than \$3 for each day of care in an institution for the care of persons suffering from chronic ailments. The exact amount of the benefit between the minimums and maximums stated, will be fixed by the Surgeon General of the Public Health Service after consultation with the National Advisory Medical and Hospital Council to be created by the bill and after approval by the Social Security Board. In lieu of such compensation, the Surgeon General may, after approval of the Social Security Board, enter into contracts with participating hospitals for the payment of the reasonable cost of hospital service, at rates for each day of hospitalization neither less than the minimum nor more than the maximum applicable rates previously mentioned. Such payments will constitute full reimbursement; the bill provides for the cost of essential hospital services including the use of ward or other least expensive facilities compatible with the proper care of the patient.

PANEL OF PHYSICIANS TO SUPPLY MEDICAL CARE

The Surgeon General will be required to publish and otherwise make known in each area to individuals entitled to benefits the names of general practitioners who have signified their willingness or desire to participate in the insurance program.

Any legally qualified physician may so participate. A beneficiary may select any physician appearing on the panel to treat him subject to the consent of the physician selected, and may change such selection in accordance with such rules and regulations as may be prescribed. The Surgeon General may set maximum limits to the number of potential beneficiaries for whom a general practitioner may undertake to furnish medical benefits. Such limits may be nationally uniform or may be adapted to take account of "relevant factors."

The services of specialists will ordinarily be available only on the advice of the general practitioner. The Surgeon General will determine what constitutes specialist services and will also determine the qualifications of physicians as specialists "in accordance with general standards previously prescribed by him after consultation with the council and utilizing standards and certifications developed by competent professional agencies."

PAYMENTS FOR THE SERVICES OF PHYSICIANS

Payments to general practitioners may be made (1) on the basis of fees for services rendered according to a fee schedule approved by the Surgeon General, or (2) on a per capita basis, the amount being according to the number of individuals entitled to benefits who are on the practitioner's list, or (3) on a salary basis whole or part time, or (4) on a combination or modification of these bases. The method of payment, subject to the approval of the Surgeon General, will apparently be determined in each area in accordance with the desires of a majority of the general practitioners collaborating with the insurance program.

Payments to designated specialists may include payments on salary (whole time or part time), "per session," fee for service, per capita, or other basis, or combinations thereof. Apparently the method of payment to be adopted for specialists will be determined by the Surgeon General.

Payments for medical services may be nationally uniform or may be adapted to take account of "relevant factors." In any area where payment for the services of a general practitioner is on a per capita basis, the bill provides that the Surgeon General shall distribute on a pro rata basis among the practitioners of the area on the panel those individuals in the area who, after due notice, have failed to select a general practitioner or who, having made a selection, have been refused by the practitioner.

The bill provides that in each area the provision of general medical benefit for all individuals entitled to receive such benefit "shall be a collective responsibility of all qualified general practitioners in the area who have undertaken to furnish such benefit."

LIMITATIONS ON GENERAL MEDICAL AND LABORATORY BENEFIT

The Surgeon General and the Social Security Board may determine for any calendar year or part thereof that every individual entitled to general medical benefit may be required by the physician attending him to pay a fee with respect to the first service or with respect to each service in a "spell of sickness" or course of treatment if it is believed that such a determination is necessary and desirable to prevent or reduce abuses of entitlement to such benefits. Maximum size of such fee may be fixed by the Surgeon General and the Social Security Board at an amount estimated to be sufficient to prevent or reduce abuses and not such as to impose a substantial financial restraint against proper and needed receipt of medical benefit. Likewise the Surgeon General and the Social Security Board may limit the application of such fees to home calls, office visits or both.

PARTICIPATING HOSPITALS

For a hospital to participate in this insurance program, it must have been approved by the Surgeon General under standards prescribed by him after consultation with the council. A hospital to be approved must provide all necessary and cus-

tomary hospital services and must be found to afford professional service, personnel and equipment adequate to promote the health and safety of individuals customarily hospitalized in such institution. The Surgeon General may approve or accredit a hospital for limited varieties of cases and may accredit an institution for the care of the "chronic sick." In determining the adequacy of the professional service, personnel and equipment of any such institution, the Surgeon General may take into account the purpose of such limited accrediting, the type and size of community which the institution serves, the availability of other hospital facilities, and such other matters as he may deem relevant.

APPLICATION FOR AND LIMITATION OF HOSPITALIZATION BENEFITS

No application by an individual for hospitalization benefits will be valid with respect to any day of hospitalization if the application is filed more than ninety days after such day, or with respect to any day of hospitalization for mental or nervous disease or for tuberculosis after such diagnosis has been made. The maximum number of days in any benefit year for which any individual may be entitled to hospitalization benefit will be thirty. If, however, the funds in the special hospitalization benefit account fund to be created prove adequate, the maximum number of days may be increased to ninety by the Surgeon General and the Social Security Board, acting jointly.

PROPOSED METHOD OF ADMINISTRATION

The Surgeon General of the Public Health Service will be authorized to take all necessary and practical steps to arrange for the availability of the medical, hospitalization and related benefits. He will be authorized to negotiate and periodically to renegotiate agreements or cooperative working arrangements with appropriate agencies of the United States, or of any state or political subdivision thereof, and with other appropriate public agencies, and with private agencies or institutions, and with private persons or groups of persons, to utilize their services and facilities and to pay fair, reasonable and equitable compensation therefor.

The methods of administration, including the methods of payment to practitioners, the bill provides, shall (1) insure the prompt and efficient care of individuals entitled to benefits, (2) promote personal relationships between physician and patient, (3) provide professional and financial incentives for the professional advancement of practitioners and encourage high standards in the quality of services furnished as benefits through the adequacy of payments to practitioners, assistance in their use of opportunities for postgraduate study, coordination among the services furnished by general practitioners, specialists, laboratory and other auxiliary services, coordination among the services furnished by practitioners, hospitals, health centers, educational, research and other institutions, and between preventive and curative services, and otherwise, (4) aid in the prevention of disease, disability and premature death, and (5) insure the provision of adequate service with the greatest economy consistent with high standards of quality.

NATIONAL ADVISORY MEDICAL AND HOSPITAL COUNCIL

The bill proposes the creation of a National Advisory Medical and Hospital Council, to consist of the Surgeon General of the United States Public Health Service as chairman and sixteen members appointed by him. The appointed members will be selected from panels of names submitted by the professional and other agencies and organizations concerned with medical services and education and with the operation of hospitals and from among other persons, agencies or organizations informed on the need for or provision of medical, hospital or related services and benefits. Appointed members will

office for four years, with the terms of office staggered. The appointed members will receive compensation at the rate of \$25 a day for time spent on official business of the council and actual and necessary traveling expenses and per diem in lieu of subsistence.

This council will advise the Surgeon General as to (1) professional standards of quality to apply to general and special medical benefits, (2) designation of specialists, (3) methods and arrangements to stimulate and encourage the attainment of high standards through coordination of the services of general practitioners, specialists, laboratories and other auxiliary services, and through the coordination of the services of practitioners with those of educational and research institutions, hospitals and health centers and through other useful means, (4) standards to apply to participating hospitals and to establishment and maintenance of the list of participating hospitals, (5) adequate and suitable methods and arrangements of paying for medical and hospital services, (6) studies and surveys of the services furnished by practitioners and hospitals and of the quality and adequacy of such services, (7) grants in aid for professional education and research projects, and (8) establishment of special advisory, technical, local or regional boards, committees, or commissions.

RELATION TO WORKMEN'S COMPENSATION ACTS

The benefits provided by this bill will not be available with respect to an injury, disease or disability coming within the purview of any state or federal workmen's compensation act.

DENTAL, NURSING AND OTHER BENEFITS

The bill devolves on the Surgeon General and the Social Security Board jointly the duty of ascertaining the most effective methods of providing dental, nursing and other needed benefits not contained in the pending bill and of determining the expected costs of such additional benefits. The bill contemplates that the Surgeon General and the Social Security Board will report the results of their findings, with recommendations as to legislation, not later than Jan 1, 1946.

GRANTS-IN-AID FOR MEDICAL EDUCATION, RESEARCH AND PREVENTION OF DISEASE AND DISABILITY

The Surgeon General will be authorized to administer grants-in-aid to nonprofit institutions and agencies engaging in research or in undergraduate or postgraduate professional education. The purpose of these grants will be to encourage and aid the advancement and dissemination of knowledge and skill in providing benefits and in preventing illness, disability and premature death. Such grants-in-aid will be made with respect to each project (1) for which application has been received from a nonprofit institution or agency stating the nature of the project and giving the reasons for the need of financial assistance in carrying it out, and (2) for which the Surgeon General finds with the advice of the council, that the project shows promise of making valuable contributions to the education or training of persons useful to or needed in the furnishing of medical, hospital, disability, rehabilitation and related benefits or to human knowledge with respect to the cause, prevention, mitigation or methods of diagnosis and treatment of disease and disability.

This part of the program will be financed by setting aside a certain percentage of amounts expended for benefits from the Federal Social Insurance Trust Fund to be created by the bill. The amount to be set aside will equal 1 per cent of the total amount expended for benefits from the trust fund, exclusive of unemployment insurance benefits, or 2 per cent of the amount expended for benefits under title IX (relating to federal medical, hospitalization and related benefits) after bene-

fits under that title have been payable for not less than twelve months, whichever is the lesser, in the last preceding fiscal year. The bill apparently leaves all the details with respect to these grants-in-aid to regulations to be promulgated by the Surgeon General after consultation with the council.

SELF EMPLOYED INDIVIDUALS

Self employed individuals may receive the benefits of the old age, survivors, and permanent disability and medical and hospital insurance by paying into the Trust Fund an amount equal to 7 per cent of the market value of their services rendered as self employed individuals, after Dec 31, 1943, with respect to services in self employment after that date but not including that part of any remuneration for employment and the market value of services in self employment in excess of \$3,000 for any calendar year.

EMPLOYEES OF STATES AND LOCAL SUBDIVISIONS

The bill authorizes the Social Security Board to enter into compacts with individual states or with political subdivisions for the purpose of extending old age, survivors, and permanent disability and medical and hospitalization insurance coverage to employees of such states or political subdivisions. To finance the benefits to be provided under such compacts the bill requires such employer to pay a social security contribution equal to 3.5 per cent of the wages paid by it after Dec 31, 1943 and every individual beneficiary of such a compact a contribution equal to 3.5 per cent of the wages received by him after Dec 31, 1943 excluding any amount paid or received in excess of \$3,000 during any calendar year after Dec 31, 1943.

BILL AS VIEWED BY SENATOR WAGNER

On the floor of the Senate, June 3, Senator Wagner described the overall objectives of his bill as follows:

The bill establishes a nationwide system of public employment offices to help war workers and war veterans to avail themselves of job opportunities in private industry and on farms throughout the country. It covers broadly the major economic hazards of average American families—the cost of medical and hospital care and loss of income in time of unemployment, temporary sickness, permanent disability and old age. It improves the present old age insurance system and extends coverage to 15,000,000 persons now excluded such as farm workers and domestic servants, employees of nonprofit institutions and the independent farmer, professional and small businessman. All these changes are established under a unified national system of social insurance with one set of contributions, one set of records and reports and one set of local offices. Reinforcing the job guaranty in the Selective Service Act, the bill gives the returning veteran and his family paid up benefit rights in every phase of this insurance protection. And finally the bill sets up an improved unified system for grants-in-aid to the states for public assistance on a variable matching basis in place of the rigid categories under present law.

PROSPECT OF SENATE CONSIDERATION OF THE BILL

Senator Walter F. George, chairman of the Senate Committee on Finance, before which S 1161 is pending, has been quoted as saying that his committee cannot possibly undertake to give consideration to the bill until late in the present session of the Congress and that if that consideration is given, and if favorable action is taken by the committee, the measure will not reach the floor of the Senate until next year.

OFFICIAL NOTES

SUMMER HEALTH HINTS

The next three programs for the new series of broadcasts over WLS on Thursdays at 2:45 p. m. under the title 'Summer Health Hints' will be as follows:

July 1	Heat and Sun
July 8	Insects
July 15	Poison Oak or Ivy

PROCEEDINGS OF THE CHICAGO SESSION

MINUTES OF THE ANNUAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN CHICAGO, JUNE 7-9, 1943

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, June 8

The House of Delegates was called to order at 9:30 a. m. by the Speaker, Dr. H. H. Shoulters.

Roll Call

On motion of Dr. Allen H. Bence, Georgia, seconded by Dr. Arthur I. McCormick, Kentucky, and carried, the House dispensed with the roll call.

Presentation of Minutes

Dr. J. Newton Himsberger, Pennsylvania, moved that the House dispense with the reading of the minutes. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, reported that one hundred and seventy members of the House of Delegates had been registered. All states, all sections and the three government services have complete registration. The only delegates who are not in attendance are those from Alaska, the Isthmian Canal Zone, the Philippines and Puerto Rico.

Report of Reference Committee on Medical Education

Dr. Wilburt C. Davison, Chairman, presented the following report, which, on motions, duly seconded and carried, was adopted section by section and as a whole.

1 The Reference Committee on Medical Education approved the following proposals:

1 Resolution on Technical X-Ray Training Courses, introduced by Dr. E. H. Skinner, Section on Radiology.

2 The changes in the Essentials of an Acceptable School for Clinical Laboratory Technicians, suggested in the supplementary report of the Council on Medical Education and Hospitals.

3 The Essentials of an Acceptable School for Physical Therapy Technicians, as presented in the supplementary report of the Council on Medical Education and Hospitals. These essentials have been completely revised in the supplementary report.

4 The Essentials of an Acceptable School of Occupational Therapy, as presented in the supplementary report of the Council on Medical Education and Hospitals. These essentials have been completely revised in the supplementary report.

5 Essentials of an Acceptable School for Medical Record Librarians, which were prepared by the Council on Medical Education and Hospitals in accordance with the request of the Board of Trustees, which had had referred to it a request from the House of Delegates at the Atlantic City session that the American Medical Association inspect and approve or disapprove present and future schools for the training of medical record librarians. These essentials as prepared by the Council on Medical Education and Hospitals are contained in the supplementary report of that Council.

6 The report of the Council on Medical Education and Hospitals, section by section and as a whole, as contained in the Handbook.

II Resolution Requesting Study of Nursing Licensure Requirements. Your reference committee, although sympathetic with the Resolution Requesting Study of Nursing Licensure Requirements, introduced by Dr. Stephen E. Gavin, Wisconsin, does not approve the resolution because it does not fall within the jurisdiction of the American Medical Association.

Respectfully submitted,

WILBURT C. DAVISON, Chairman
WALTER G. PHIPPEN
ROBERT E. SCHLUETER
CHARLES H. PHIFER
LEON J. MENVILLE.

Report of Reference Committee on Hygiene and Public Health

Dr. Warren F. Draper, Chairman, presented the following report, which, on motions duly seconded and carried, was adopted section by section and as a whole.

1 Resolutions on Giving Intelligent Instruction in Science and Biology to the Youth of America. With the consent of Dr. Borzell, the committee made certain changes in the resolutions, which now read as follows:

WHEREAS, The appropriate teaching in the secondary schools of science including biology, is essential to the child's understanding of health and nutrition, and

WHEREAS, The medical profession is vitally interested in such education therefore be it

Resolved That the American Medical Association endorse the principle that every child in the United States be given adequate, sound instruction in high school in basic science including at least one year of biology, and be it further

Resolved, That the American Medical Association through its Bureau of Health Education encourage close cooperation between the constituent state medical associations and component county medical societies and the teachers of science in their respective communities to the end that intelligent instruction in science and biology be given the youth of America.

Your reference committee has been informed that national organizations which have already endorsed this principle are the American Association of Physics Teachers, American Chemical Society, Mathematical Association of America, Union of American Biological Societies and National Association for Research in Science Teaching.

The importance of real health education of the proper type in the schools has been forcibly demonstrated by the results of the physical examinations for the draft boards.

Teaching such as indicated is a fundamental necessity for the proper understanding of the elements of health and physical well being.

A sound educational basis in the sciences will help to sensitize the student to pseudoscientific claims, cultism and quackery.

Your reference committee has ascertained that the resolutions are practicable from the standpoint of the Bureau of Health Education and recommends their adoption as now presented.

2 Report of Bureau of Health Education as presented in the Handbook, pages 70 to 77. Your reference committee commends the Bureau of Health Education on its accomplishments under the trying conditions of the present time.

It is interesting to note that the travel of the director has necessarily been greatly curtailed and that the Bureau has turned to the radio to carry on much of the work that needs to be done. Direct broadcasts are made in some instances and recordings are also developed. Master records are made with ten recordings of each. These are sent out to constituent state medical associations and component county medical societies and may be used on the air at their convenience.

The adaptation of the radio program to cover the war work of doctors is especially commended. In the opinion of your reference committee, the results of this program are of definite value and its development should continue.

1 Report of Council on Industrial Health is presented in the Handbook, pages 65-70. Your reference committee notes with especial satisfaction the work of the Council in developing a plan for the recruitment and placement of medical volunteers for service in essential war industry. The committees on industrial health of constituent state medical associations can be of great assistance to the chairmen and state committees of procurement and assignment of physicians in furnishing medical service in industry.

This is one of the younger councils, which because of the character and excellence of the work that it is doing, is making itself felt and is becoming increasingly important.

Respectfully submitted,

WARREN F. DIALER, Chairman
HOLMAN TAYLOR
DON F. CAMERON
RANDOLPH D. BERNARD
WALTER W. KING

Report of Reference Committee on Miscellaneous Business

Dr. Charles G. Strickland, Chairman, presented the following report which on motions duly seconded and carried after discussion was adopted section by section and as a whole:

1 Resolution on Having Copies of the Boy and Girl Scouts Manual in Physicians' Waiting Rooms, approved by the Louisiana State Medical Society and introduced by Dr. James Q. Graves, Louisiana. Your reference committee recommends the rejection of this resolution. The boy scouts and the girl scouts are both worthwhile organizations and their value in youth training and in character building is unquestioned. Nevertheless, your reference committee hesitates to recommend favorable action on this resolution, since other worthy organizations may request similar action on their literature and once the precedent is set the flood gates are open. The choice of waiting room reading can be left safely to the judgment of the individual physician and the taste of his clientele.

2 Resolution Requesting Constituent Associations and Component Societies to Consider the Establishment of Some Form of Dues for Their Members in Service, introduced by Dr. James C. Sargent, Wisconsin. Your reference committee desires to express its high appreciation of the motives which actuated the introduction of this resolution. The line of reasoning used does Dr. Sargent great credit. However for many reasons, too obvious to detail, your reference committee recommends that this resolution be rejected.

Respectfully submitted,

CHARLES G. STRICKLAND, Chairman
ALBERT A. GARTNER
H. A. LUCE
JAMES W. HAYES
STEPHEN E. GAIN

Introduction and Address of Brig Gen David N. W. Grant

President Fred W. Rankin presented to the House Brig Gen David N. W. Grant, Flight Surgeon, as follows:

Mr. Speaker and Members of the House: As you are aware the Army of the United States is divided into three component parts, Air, Ground and Service of Supply. Each of these branches has its own medical service and each of them has expanded enormously and their medical services have expanded

alongside of them. I believe it is fair to say that the Air Corps has expanded more rapidly and more efficiently and more centrally than any other arm of the service. That is particularly true of the medical service of the Air Corps, because a year and a half ago I think I am correct in saying there were 97 flight surgeons in the Army. Today there are 9,300 flight surgeons in the Army.

In this expansion and in the development of the fine *esprit de corps* that the flight surgeons have and the especially fine cooperation that exists between the flight surgeons and the fliers and the men who serve the fliers, I think we can unquestionably pay tribute and give credit to the present Air Surgeon Brig Gen David N. W. Grant. He has developed an extraordinarily efficient staff. He has been exceedingly far reaching in his planning and to him goes an enormous amount of credit for the present day efficiency and the splendid all round rating of the Air Corps, the medical portion of the Air Corps.

General Grant is not a desk general. He has been in every theater of major activity in which our troops now operate, and I am privileged to present him to this House at this moment. Brigadier General David N. W. Grant.

Brig Gen David N. W. Grant addressed the House as follows:

Mr. Speaker, General Rankin and Members of the House: General Rankin has been most flattering in his comments but I cannot accept the full credit and responsibility. I leave it to you to say who has done this job. It has been and continues to be the people of this Association who have come to the fore and rendered full cooperation.

I feel particularly honored in being here. Today represents the culmination of about twelve years of hard work and my presence at this meeting is only symbolic of the deserved recognition of aviation medicine, a medical specialty which has had a hard struggle through the years. Aviation medicine has not received due recognition until just recently. We have had almost an absolute neglect of the medical aspect of the flier, due perhaps to some indifference and lack of funds, means and facilities. Of course this war has brought the entire situation to a head.

The development of the Army Air Forces Medical Service has been extremely interesting. It was a new creation. We had nothing to go on and very little past experience in which to base judgment. I have always thought of aviation medicine as being a return of the old family doctor. It is a specialty, yes, but the old family doctor was a specialist too. I like to feel that we are contributing a great deal to the future of medicine in the United States through our hope of returning physicians to civilian life not with an appreciation of a special part of the individual but with recognition of the individual as a whole and of treating him as a whole. I think the tendency in medicine has been to specialize perhaps to too great an extent. I have come in contact for instance, with heart specialists who couldn't listen to the lungs. It isn't that I don't believe in medical and surgical specialists because I do, but I think that they should expand a bit and not consider just a part of the individual but should study the patient as a whole, both as to diagnosis and in treatment.

In considering the development of the medical services of the Army Air Forces I feel very strongly that if we don't return the physicians who are with us to civilian life at least on a par with what they were when they came to us or as better doctors, we shall have failed in our mission. For this reason we have sent a great many of our medical men to special schools. The figure is a little over 5,000 in the Army Air Forces alone. We have started an intern and resident program which as you know was announced in *THE JOURNAL* several weeks ago. We want to give the interns and residents coming to us a chance and we are going to give it to them. Those boys who show ability are going to be advanced and trained under recognized men. We hope the various boards will give them due credit when these young men come to them.

The medical profession has been very kind to us. Without exception we have had the full support of all the professional

organizations. Otherwise we could not have done the job with which we were faced. We have tried to build an *esprit de corps* in our doctors of the same magnitude that exists in the Army Air Forces as a whole and we have built an enviable relationship between our doctors and the Army Air Forces personnel to the benefit of both concerned. I know that in the majority of cases our doctors are happy in their work. Of the men recognized by boards, or of those eligible for their boards, 98.77 per cent of the 1,785 with us are practicing their specialties. I believe that this move alone has saved the Army Air Forces 500 to 1,000 doctors by placing the right person in the right place.

I want to assure the American Medical Association that the Medical Service of the Army Air Forces appreciates the position of the doctor from civilian life. We are trying our best to place him properly and to keep him content and as happy as conditions permit. We all have recognized that there are many, many tasks in the Army that must be done and that there will be some misplaced personnel. It can't be helped in all instances, but we are making an honest endeavor to see that the civilian physician who is with us and who, after all, is doing the work is placed in the field for which he is best fitted.

Dr. Arthur I. McCormick, Kentucky, moved that this statement be read, affirming the sound principles that it does be referred to the Council on Medical Education and Hospitals with the commendation of the House. The motion was seconded by Dr. William Weston, Section on Pediatrics, and carried.

Report of Reference Committee on Sections and Section Work

Dr. Francis F. Borzell, Chairman, presented the following report, which was adopted on motion of Dr. Borzell, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

There was but one item of business referred to your reference committee, and that was the report of the Council on Scientific Assembly, which, although brief, deals with the major function of the American Medical Association, that of promulgation of medical science.

The manner in which the serious problem of providing suitable material for journalistic publication has been met and the impetus given to continue postgraduate instruction to service men and civilian doctor alike deserves special approval.

Your reference committee therefore recommends the adoption of this report with commendation for the foresighted policy enunciated and the practical method of solving a difficult problem.

Respectfully submitted,

FRANCIS F. BORZELL, Chairman
L. G. CHRISTIAN
OLIN H. WEAVER
BENJAMIN F. COOK
ARTHUR J. BEDELL

On motion of Dr. George W. Kosmak, New York, duly seconded and carried, the House recessed for ten minutes at 10:08 a. m., to give the typists an opportunity to finish typing reference committee reports.

The Speaker called the House to order at 10:20 a. m.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Walter E. Vest, Chairman, presented the first two sections of the report of the Reference Committee on Amendments to the Constitution and By-Laws, the third section being postponed until the Executive Session of the House on motion of Dr. E. H. Skinner, Section on Radiology, and so ordered, without objection, by the Speaker.

Your Reference Committee on Amendments to the Constitution and By-Laws met twice, considered all matters referred to it and offers the following report:

1. The Report of the Judicial Council. While not involving amendments to the Constitution and By-Laws, the report of the Judicial Council is very thought provoking and makes us realize the delicate position we now occupy in the eyes of the populace and the necessity for considering well our every move as a

profession. Your reference committee is especially impressed with the care the Council exercises in approving applicants for Fellowship and it commends the entire report to the profession generally.

2. Proposed Amendment to Constitution, Article 5, Section 2, contained in Report of the Secretary as published in the Handbook. Your reference committee has given very careful consideration to that part of the Report of the Secretary relating to the proposed amendment to the Constitution, article 5, section 2, submitted to the House of Delegates by the reference committee on Sections and Section Work at the annual session last year. Your reference committee believes that the adoption of this proposed amendment would be very unwise and essentially destructive, inasmuch as it would tend to change the character of the House of Delegates from a scientific body to a political and economic body. The American Medical Association is, and ought to be, a true composite of the entire medical profession of the United States. It is not only a federation of constituent state and territorial medical associations but includes as well the national governmental medical services as units, and the separate units of the Scientific Assembly, i. e., the sections. Such an amendment would tend to make the Scientific Assembly less cohesive. The very nature of the Scientific Assembly and its sections demands that the section delegates have full rights including the right to vote, otherwise the point of view of the specialties and the individual sections cannot be properly presented, and the business of the sections cannot be properly transacted. The section delegates, in the judgment of your committee, should be more than mere liaison officers, they should be actual, vibrant members of the House of Delegates invested with all the rights and privileges accorded to the delegates representing the various state and territorial associations. Your reference committee recommends, therefore, that the proposed amendment to the constitution be not adopted.

Respectfully submitted,

WALTER E. VEST, Chairman
LOUIS A. BUIE
KARL S. J. HOHLEN
WILLIAM WESTON
ELBERT G. WOOD

Dr. Vest moved the adoption of the first section of the report of the reference committee recommending approval of the report of the Judicial Council. The motion was seconded by Dr. Elbert G. Wood, Tennessee, and carried.

It was moved by Dr. Vest, seconded by Dr. Arthur T. McCormack, Kentucky, and carried after discussion by Drs. McCormack and Vest, that the House adopt the second section of the report of the reference committee recommending that the proposed amendment to article 5, section 2, be not adopted.

On motion of Dr. Vest, seconded by Dr. John Z. Brown, Utah, and carried, the report of the reference committee was adopted as a whole.

Report of Reference Committee on Reports of Officers

The Vice Speaker presided while the first section of the report of the Reference Committee on Reports of Officers was read, after which the Speaker resumed the Chair.

Dr. Deering G. Smith, Chairman, presented the following report, which was adopted section by section and as a whole, on motions of Dr. Smith, duly seconded and carried.

1. Address of the Speaker. Your reference committee feels sure that it voices the sentiment of the entire House in expressing its appreciation of the loyal and efficient leadership of our Speaker. It is pleased that he is emphasizing the work of the reference committees, and it reiterates his plea that members of the House of Delegates and the Association attend and participate in the reference committee meetings. It wishes to thank him for his appreciation of the work and accomplishments of the members of the House of Delegates and assure him of our best efforts to deserve to be called medical statesmen. It is reassuring that the medical statesmanship of the past has contributed to our present high standard of medical care of the war casualties and of the civilian population. Your reference committee agrees with Dr. Shoulders that such a

state-manship must continue if the problems of the future are to be solved

2 Address of the President Our President has had the most difficult task of leading the Association during this year of the war and also holding a high position in the Office of the Surgeon General of the Army. He has discharged his manifold duties with credit to himself and to the benefit of organized medicine. He has had an unusual opportunity to gain a comprehensive view of the medical problems as they are related to the physician, the state and the people. In his scholarly address he has set forth certain broad concepts which should be carefully studied by every member of the profession.

He has charged us with the responsibility of approaching the problems of medical care in a thoroughly cooperative spirit. He further expresses the opinion that to achieve these solutions the American Medical Association should set up the necessary agencies. It is expected that the Committee on Planning of Postwar Medical Services will be such an agency.

3 Address of the President Elect (a) Your reference committee is conscious of the time and effort expended by the President-Elect in the affairs of organized medicine and it expresses appreciation of this sacrifice.

It is noted with interest that twelve to fifteen million people under the American voluntary system have procured for themselves protection against the expense of major illness. This is an example of how the American people under proper leadership and education will provide for themselves without the undesired intervention of a paternalistic government.

Your reference committee commends Dr. Pullins' efforts in the provision of continuing medical education for our members now in service and for the civilian physicians who have been deprived of attendance at the customary Scientific Assembly. It recommends that this House of Delegates approve the Wartime Graduate Medical Training program and suggests that after the war it may be advantageous to incorporate it in the peacetime system of postgraduate instruction.

(b) Your reference committee notes with enthusiasm the formation by the Board of Trustees of the temporary Committee on Planning of Postwar Medical Services which action it recommends be approved by the House of Delegates.

(c) Your reference committee further recommends that the Board of Trustees be instructed to make this a permanent committee on Planning of Postwar Medical Services to cooperate and collaborate with other agencies concerned with these problems.

Respectfully submitted

DEERING G. SMITH Chairman
FLOYD S. WINSLOW
JOSEPH H. CANNON
WILLIAM R. BROOKSHER
EDWARD JELKS

The Speaker announced that he had consulted with the chairman of the Reference Committee on Rules and Order of Business and that he was told that it was that chairman's opinion that the same regulations in the By-Laws that usually apply to the meeting of the House on Thursday or the week of the annual session would apply tomorrow (Wednesday) this year which means that no new business may be presented at tomorrow's meeting unless it comes from the Board of Trustees, the officers of the sections or the sections except by unanimous consent. This opinion was confirmed on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, duly seconded and carried after discussion by Drs. Allen H. Bunce, Georgia; Holman Taylor, Texas; Arthur T. McCormack, Kentucky; R. W. Fouts, Vice Speaker; John Z. Brown, Utah; and the Speaker.

On motion of Dr. Edward H. Cary, Texas, duly seconded and carried, the House recessed from 10:50 a. m. to 11 a. m.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Louis H. Bauer, Chairman, presented the report of the reference committee, which on motions of Dr. Bauer, duly seconded and carried, was adopted section by section. That section of the report of the reference committee dealing with hospital corporations engaging in the practice of medicine being amended, and as a whole as amended.

REPORT OF THE SECRETARY

1 Membership and Fellowship Once again your reference committee is pleased to note an increase in the membership of the Association which now totals more than 123,000, or an increase in ten years of over 25,000. The committee agrees with the Secretary that it refutes an old made charge that physicians as a whole are not in accord with the Association. Your reference committee feels that there is probably no organized body which has been so slandered by outsiders who do not know the true facts as has been the American Medical Association.

There has been a decrease of 8% in the Fellowship class, but considering that there are 45,000 physicians in the armed forces this decrease is surprisingly small. It is evidence that the House acted wisely a year ago in making no recommendation to revise the Constitution and By-Laws to permit remission of Fellowship dues and that the great majority of Fellows wish to maintain their subscription to the various journals of the Association in order to keep abreast of the changes in medicine.

2 Cancellation of Annual Session Your reference committee feels that the Trustees acted wisely in canceling the annual scientific session and having a meeting only of the House of Delegates and of the councils in view of war conditions, particularly as to transportation and the general shortage of physicians.

3 Correction of the Minutes Correction of the proceedings of the 1942 session of the House of Delegates was requested by Dr. Arthur J. Bedell, Section on Ophthalmology, but as this has already been taken care of by the House on June 7, 1943, no further action is necessary.

4 Annual Conference of Secretaries and Editors of Constituent State Medical Associations This conference is an annual affair and in these times is especially important in order that all war activities as well as routine matters of the various constituent associations may be properly coordinated. These conferences should be continued through the war unless transportation restrictions become so acute that it is not feasible. Special thanks should be expressed by the House to those government officials who have attended these conferences and helped in their success.

5 Service of the Secretary The Secretary again has expressed his thanks to all those with whom he has been officially associated. Your reference committee notes that this year completes twenty-one years of service by Dr. Olin West as Secretary. To express what the House in particular and organized medicine in general owes to him would be impossible, but your reference committee recommends that the House express its thanks and its best wishes for continued service from him.

REPORT OF BOARD OF TRUSTEES

If any member of the House has not read the report of the Board of Trustees, he owes it to himself and the organization he represents to do so. As usual, it contains a great deal of informative material.

1 Income and Expenditures It was fully expected a year ago that the income of the Association would be materially reduced by the exigencies of the war. Your reference committee notes with great satisfaction that such is not the case. The total income is greater by over \$36,000 for 1942 than for 1941. The Board of Trustees also reports a reduction in the total expenditures for 1942 over 1941 of nearly \$71,000. Another unexpected source of income was from Fellowship dues and subscriptions. While it was expected these would decrease, there was an actual increase of nearly \$9,000. This is particularly gratifying as it evidences a feeling of those in the armed services that they must have the Association's publications. Again, it was felt a year ago that income from advertising space in THE JOURNAL might and probably would be decreased. Instead of that, there has been an increase of well over \$26,000. However, your reference committee feels it must caution the House that continued increases cannot be expected. We probably have not yet felt the full impact of the war effort and restrictions of advertising may yet well occur, as well as further restrictions in the use of paper.

A falling off in the income from investments of about \$3,000 is noted and this must be expected, and, in fact, there may be a still greater reduction next year.

There has also been an increase in the cost of paper, which will be felt still more during the current year as new stocks are purchased. The Trustees have cooperated with the government by cutting down the size of publications and the paper margins and by the use of lighter weight stocks. It is hoped that it will not be necessary to curtail the amount of the scientific content, but even this may occur.

As indicated a year ago, salaries and wages have increased. This cannot be avoided, and further increases may be necessary, particularly as the work of the Association has been tremendously increased by its participation in war activities.

Operation of the councils, bureaus and departments of the Association has increased in cost by a little over \$7,100, doubtless because of war activities.

The legal and investigating expense has decreased by about \$55,000. This has been due to the fact that a year ago the costs were great because of the suit against the Association by the government.

As a whole we can look on the financial status of the Association as excellent, and the Trustees should be commended for their excellent handling of the finances of the Association. While income may yet fall off before the war is over, the increases in income during the past two years will afford an excellent backlog without the Association having to dip too deeply into its principal to maintain its activities on the present level.

2 THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Your reference committee recommends approval of the action of the Trustees in giving special consideration to the problems of war medicine and war effort as a whole. It also notes with satisfaction that the Trustees have arranged with the scientific sections for a continued flow of material for publication in spite of the cancellation of the annual scientific session.

Your reference committee also recommends continuance of the organization section of *THE JOURNAL* on its present plan.

Your committee also approves the action of the Trustees in appealing to the War Production Board on the reduction of paper used by 10 per cent, as *THE JOURNAL* and its contents are certainly a contribution to the war effort.

While there has been a slight reduction in the total circulation of *THE JOURNAL* during the past year, it is surprisingly small and, were it not for the cancellation of foreign subscriptions naturally to be expected, the circulation would be larger rather than smaller.

3 Special Journals. A year ago it was reported that two of these nine journals were operated with an income above the cost of publication. This year four of them have been so operated. Total circulation of these journals has slightly increased, the increase being due partly to *WAR MEDICINE*, which increased its circulation by 33 per cent. In view of the war situation, these facts are very encouraging.

4 HYGEIA. This magazine also increased its income by over \$40,000. Wider distribution among the laity would serve as an excellent means of education and help counteract the propaganda of cultists and faddists. This increase in income has been largely due to the activities of the Woman's Auxiliary, and our thanks are due that body.

5 Library. The library has continued its usefulness, and there has been special call for articles with reference to war medicine. It is believed by your reference committee that more extended use would be made of the library if *THE JOURNAL* from time to time would print a notice calling attention to its availability and the character of the service it can render.

6 Standard Nomenclature of Disease and Standard Nomenclature of Operations. The third edition of the Standard Nomenclature of Disease and the first edition of Standard Nomenclature of Operations, combined in a single volume, have been issued. This useful volume should be of interest not only to hospitals but to every physician.

7 QUARTERLY CUMULATIVE INDEX MEDICUS. This publication, one of the most valuable in medicine, has suffered a severe setback in that only about half as many articles were indexed

in 1942 as in 1941. This is because of the difficulty in obtaining foreign journals. However, as a result, the cost of and the loss sustained in publication were considerably less. Your reference committee feels that publication should continue in spite of its incompleteness, and it is hoped that after the war the deficiencies in the INDEX can be made up.

8 American Medical Directory. The publication of the seventeenth Directory was delayed unavoidably by war conditions, and the Board of Trustees feels that the next edition, which would ordinarily be published in 1944, may have to be considerably postponed. Your reference committee feels that the time of publication of another directory should be left to the judgment of the Trustees and so recommends.

9 Mailing and Order Department. Attention is merely invited to the tremendous amount of mail handled by the office of the Association.

10 Cooperative Medical Advertising Bureau. This was the most successful year of the Bureau from the financial standpoint. The Bureau continues to be of great value to many state journals.

11 Press Relations. The ramifications of the Press Relations activities of the Association continue to increase. The *AMERICAN MEDICAL ASSOCIATION NEWS* is reaching a constantly increasing number of agencies. Press stories based on *THE JOURNAL* and *HYGEIA* totaled over 83,000 in 1942, an increase of nearly 2,000 over 1941. An increasing number of feature stories and editorials and radio broadcasts based on information furnished by the Association is noted. Over 3,800 inquiries were answered, an increase of 700 over 1941. The Press Relations activities have also played a large part in the war activities of many organizations, including the government. These activities of the Association deserve commendation and should be continued. It is through such relations that much of the vicious propaganda against American medicine can be combated.

12 Council on Pharmacy and Chemistry. During the past year the Council has increased its contributions to the welfare of the physician and the public and has given material aid to many agencies of the federal government in prosecution of the war effort. Furthermore, it has held a meeting with representatives of the American Pharmaceutical Association and established cooperative relationships with a number of foreign countries. Several of the publications of the Council have been revised during the year and there is an increasing demand for them. The Council has continued research through various grants, and valuable information on new methods of treatment is expected. Forty-four reports and twenty monographs on drugs have been issued and many more drugs are under study.

At the annual meeting of the Council, among the matters discussed were prevention and treatment of fungous infections, promotion of mixed vitamins, labeling of vitamin preparations, mineral waters, contraceptives, use of the metric system, scope of New and Nonofficial Remedies, medical and pharmaceutical relations, and censorship of published descriptions of new drugs, the last named being required by the Office of Censorship. Your reference committee is glad to note that further attention has been given to the subject of vitamins in accordance with the expressed wishes of the House a year ago. Several changes have been necessitated in the personnel of the Council because of death and resignations. Your reference committee notes that 1942 completed the thirty-eighth year of this council. The Council is to be commended for its activities and productive efforts. Your reference committee urges that still further clarification be made of the use of vitamin therapy and decries the commercialization of this important subject by some commercial organizations.

13 The Chemical Laboratory. This laboratory, now in its thirty-seventh year, is one of the mainstays of the Council on Pharmacy and Chemistry. A great deal of work has been accomplished the past year on vitamin K and testing and setting up standards for numerous drugs both old and new. Its equipment has been increased and it is now outstanding among well-equipped laboratories. The Laboratory has cooperated with all departments of the Association and with a number of other organizations. Its work deserves commendation.

14 Council on Foods and Nutrition A new load has been thrown on this council by the war because of the important food problems which have arisen in connection with it. The Council has been in close touch with the government agencies charged with promulgation and enforcement of orders pertaining to foods. In cooperation with the Council on Industrial Health a Cooperative Committee on Nutrition in Industry has been established. A great deal of further work has been done on vitamins and as a result opinion has gradually crystallized on the question of fortifying foods with vitamins and minerals. Your reference committee is glad to note that the policies of governmental agencies have been largely in harmony with those of the Council. In cooperation with the Council on Pharmacy and Chemistry and the Council on Industrial Health reports have been made on the proper use of vitamins in mixtures and the administration of vitamins to industrial workers. This work has been very timely and it is urged that the Council continue its research and educational activity in this field. In the opinion of your committee vitamins should be available on the basis of food and not on the basis of drugs. Efforts should be made to make them available at a lower cost to the public whenever a physician feels that it is essential to prescribe them. Consideration has been given to the substitution of food ingredients and the Council has felt that it was preferable as a rule to produce less rather than to diminish nutritional quality through substitution. Reports have also been issued on maintaining nutritional standards in formulation of mixed vegetable juices and on comparative nutritional value of butter and oleomargarine. It is recommended that the activities of the Council be approved and commended.

15 Council on Physical Therapy The Council has devoted much of its time to presentation of useful reliable and factual information about physical therapeutic methods for the attention of civilian army and navy physicians confronted with the task of rehabilitation. The Council has cooperated with government agencies by giving advice on physical therapeutic procedures and apparatus. In cooperation with a subcommittee of the National Research Council the Council has prepared a manual on physical therapy and with other groups is preparing one on occupational therapy which will be of value to those concerned in rehabilitation. A Handbook of Amputations has also been issued and is of value to both military and civilian physicians. The Council consultants aided in revising the curriculum for schools of technicians and in investigation of audiometers and hearing aids and has published specifications for a home made respirator. Application of ultraviolet radiation for disinfection was studied and a statement on the problem was published. The booklet Apparatus Accepted was revised. Grants were made for research on problems vital to physical therapy. Twenty-one reports were published during 1942.

The members of the Council and its consultants who receive no remuneration have given a great deal of time and effort to the work of the Council and deserve the House's thanks and commendation.

16 Bureau of Medical Economics A In carrying out the plan for a national emergency adopted by the House in 1940 the Bureau of Medical Economics was designated as the agency to conduct the census of the medical population. This entailed a tremendous amount of work and resulted in an increase in the staff of the Bureau. This census became of incalculable value to the Procurement and Assignment Service when it was established. The Bureau at first acted as a consultant office or that service. At the end of 1942 it was deemed advisable to separate the two entirely and the census was given over to Army and Civil Service personnel at the close of 1942.

B (a) Prepaid medical service plans were studied and analyzed in addition to the work connected with the war already referred to. The report of the Bureau reviews the history of the subject the earliest plans being the unit system arrangements in the states of Oregon and Washington. By the summer of 1941 about twenty state medical societies had taken steps to introduce statewide plans. Besides Washington and Oregon at the present time there are eight other states which have developed plans with the support of their state medical societies. California New Jersey Michigan Pennsylvania Colorado

North Carolina and Massachusetts each have one plan. New York has three. It is interesting to note that in 1935 there were over two hundred suggested methods. The Bureau feels that certain fundamentals ought to characterize all plans and is of the opinion that its report of 1935 is no less applicable now than then. In that report it listed ten dangers to be avoided in any plan. The Bureau again stresses these ten points which your committee feels are well worth stressing. They should be familiar to every member of the House, so that they will not be repeated in toto here. All ten are important but your committee does wish to lay special emphasis on two of them namely numbers 8 and 10. These are the freezing of medical fees at a point below that which is consistent with good medical care and 'medical society plans must not be considered or accepted as a substitute for the regular practice of medicine as applied to the majority of people. It is believed such plans may be useful they should be considered merely as supplementary facilities in the distribution of medical service. They should be used only so long and in such a manner as they serve efficiently to make more easily available to low income groups a high quality of medical care. The Bureau also has repeated that portion of its 1935 report dealing with vital factors to be recognized and protected. The substance of these factors is the avoidance of competition and to quote the report the medical profession in its professional associations is the only possible body that can organize the supply and distribution of that service without harmful effects on and possible destruction of that service itself.

(b) Experience with medical service plans has developed some interesting facts.

(1) The offering of a prepayment medical service the quality of which is guaranteed by the medical profession increases the demand for medical care much more than any one anticipated.

(2) The public's sales resistance has an important effect on the success of the plan. Premiums must be within the limits of the valuation placed by the average person on the preservation of his health. Education of the public is an important factor in solving this problem.

(3) Actuaries, physicians and consumers cannot determine accurately the effect of various contract provisions on the minds of possible purchasers of prepayment medical care.

(4) Some subscribers will always be trying to get something in return for their money and thus may overthrow the most careful actuarial calculations. In turn this may result in a tendency to restrict the amount of care or on the other hand to dilute it and make it poor and ineffectual. The Board feels that the objective should be to guard against abuse and encourage use.

(5) Unnecessary surgery may be performed by unscrupulous physicians. This must be curbed by courageous and efficient medical organizations.

(6) The type of clientele served may affect the success of the plan. This makes it impossible to adopt a nationwide plan or in some cases even a statewide plan.

(7) Income is an important factor. The original decision to limit plans to low income groups has resulted in sales resistance. Key men in industry are not interested in fostering plans which do not protect them.

(8) Income limits also have a bearing on the comparative desirability of indemnity or service benefits and has led to the development of a so-called surgical plan.

(c) Actuarial difficulties have led to the development of limited plans. The public seems unwilling to pay the cost of unlimited care. An advantage of the limited plan is that it covers so called catastrophic illnesses and these are more easily figured from the actuarial standpoint. On the other hand rural areas are not well covered by such a limited plan because of often inadequate hospital facilities. The public must be educated to realize the value and cost of complete medical service before such complete service can be developed. Such education will help combat the deceiving propaganda for compulsory insurance. A special committee of the Massachusetts Medical Society stated: Your committee urges a gradual approach to our ultimate ideal—total medical coverage by a comprehensive policy—through well defined initial steps of

partial coverage" This recommendation should be considered carefully by all states in the opinion of your own reference committee Again your reference committee reiterates the statement of the Bureau of Medical Economics that professional supervision of all the standards of medical service must be made one of the dominant features of prepayment services as it always has been of private practice

(d) Medical service plans of the Farm Security Administration have been universally reported as being conducted in accordance with the principle that the medical profession should control all features of medical service in any method of medical practice

The Bureau of Medical Economics has therefore included in its report a summary of the history of prepaid medical service, repeated the basic principles previously adopted by the House and given a summary of the experience with different plans The Bureau has carried out its function as a clearing house in the development of plans for prepaid medical service The publication of this report will be of great value to those who are intimately concerned with such plans These plans are still in the process of trial and error, but much good has developed from them However, further experimentation will be necessary The Bureau should cooperate in every way possible with those who are developing plans In the opinion of your reference committee therefore, the Bureau is correct in not attempting to draft a nationwide plan because of the varying conditions in different states It should continue to do just what it has done during the past year Approval of its work is recommended

C The Bureau notes with alarm the possibility that lack of funds may prevent the compilation and publication of basic statistical tables in connection with the latest decennial census of the United States Your reference committee agrees and recommends that the House refer the matter to the Board of Trustees for such action as seems most practicable in urging the government to allocate sufficient funds to the Census Bureau so that the latest census may be as reliable and informative as the preceding ones

17 Bureau of Investigation During the past year the bureau has continued its educational work with both the profession and the public in "patent medicines," quacks, frauds, fakes and faddists While inquiries from physicians have fallen off, those from students have greatly increased Eight thousand four hundred items have been inquired about The bureau has continued its contributions to *THE JOURNAL*, in the form both of original articles and of abstracts One thousand seven hundred and seventy-five pamphlets have been distributed and many addresses made by the director of the bureau The bureau has also cooperated with governmental and civic organizations concerned with the war effort Your reference committee commends the work of the bureau and urges continuance of its activities along the same lines

18 Bureau of Exhibits Attention is invited to the report of the bureau on the scientific exhibits at the Atlantic City session, where there was a total of 216 exhibits and four motion picture theaters in continuous operation Loan exhibits were sent out during the year ninety-one times to fifty-eight meetings A total of fifty-six exhibits are now available Twenty-six motion pictures are also available for loan They were sent out 245 times Many hundreds of requests for information have been answered and books and pamphlets have been prepared for distribution The bureau makes no recommendations, but its work is deserving of commendation

19 Committee on Student Health This committee was appointed at the suggestion of government officials, has had two meetings and reports progress

20 Committee on the Conservation of Vision This committee has also been appointed this past year, but, because of the war, its plans are not complete and will be reported later

21 Progress Report of the Committee to Study the Relationship of Medicine and Law In compliance with a resolution of the 1941 House, a committee was appointed for this purpose Two meetings have been held and the work is being carried on

in collaboration with the American Bar Association The committee considered as its most important topic those closely integrated medical and legal activities which have as their common purpose the investigation of deaths in the interests of justice and public safety The subject was divided into three parts and each assigned to a subcommittee A preliminary report was drawn up and as a result of it the committee is now conducting a survey of the relative costs of operating coroner and medical examiner offices and also is drawing up various types of model legislation for the improvement of coroners' or medical examiners' offices Several months will be required to complete the studies and render a report Your reference committee recommends that the committee be continued in order to complete its work

22 Committee on Inter-American Relations The Board of Trustees recommends that a Committee on Inter-American Relations be created in the interest of friendly relations with the medical profession of the countries of North and South America Your reference committee recommends that this request be approved

23 Committee to Study Air Conditioning Progress has been reported by the committee to the Board of Trustees, but the nature of existing conditions makes it advisable that the report be withheld from publication at present The work should be continued, and your reference committee so recommends

24 Committee on American Health Resorts The war has interfered with the work of the committee, which has, however, revised its rules for listing health resorts and is continuing the preparation of scientific papers The committee should be continued so that the work which has been started can be carried on in the interest of further development and regulation of American health resorts

25 Hospital Corporations Engaging in the Practice of Medicine This supplementary report deals with three resolutions introduced in the 1941 and 1942 houses The first related to certain group hospitalization plans, including certain medical services, contrary to the expressed policies of the House of Delegates, and called for a clarification of the existing relations between physicians and hospitals The second called for the appointment of a committee to confer with the national hospital associations on the differentiation between medical and hospital services so that the physician-patient relationship of the pathologist, the radiologist and the anesthetist may be preserved The third asserted that the practice of certain insurance companies in paying for medical services under policies covering hospital and health insurance might lead to the inclusion of physicians' services in hospital bills

All three resolutions were referred in whole or in part to the Board of Trustees The Board, after reviewing the previous actions of the House on the same subjects, came to the following conclusions

(1) In the solution of a given abuse, whether concerned with exploitation of the physician or with exploitation of the patient actual facts must be established and local conditions must be understood before the adjudicating body can act Constituent associations and component societies are in a better position than are the national bodies to obtain and to act on these cardinal necessities

(2) Conditions vary widely in the respective jurisdictions requiring the weighing of circumstances before the letter of the principle or the approved action of the House of Delegates can be equitably applied

(3) The local society is better able than is the national body to do justice to a situation that is colored by so many factors

(4) No new principles are involved in the resolutions under consideration, and no new pronouncements would appear to be necessary

(5) The responsibility for the correction of abuses rests primarily on component county medical societies and constituent state or territorial medical associations empowered to govern themselves in local matters, while they may reasonably be expected to abide by the authority of the House of Delegates in matters of general policy

(6) The obligation to prevent the exploitation of the patient while protecting the prerogatives of the physician bears with equal responsibility on our profession

(7) Special societies are in position to help in the equitable solution of these urgent problems by securing the understanding and cooperation of their members. Attempts to devise remedial measures at the national level would appear to be unwise

Before discussing these further, we must take into consideration the Supplementary Report of the Board of Trustees on the Report of the Proceedings of the Joint Committee Meeting of National Hospital Associations and Representatives of the Board of Trustees of the American Medical Association. This report deals with the same general subject.

This report is lengthy and represents a prodigious amount of work. Even though the report is lengthy, it behooves every member of the House or Delegates to read and study it carefully. The factual data contained therein concern the whole nature of the practice of medicine. Unless the medical profession as a whole is willing to devote at least the same amount of time and effort in studying the report and correcting the dangers pointed out therein as the Board of Trustees has in compiling it then we might as well throw in the sponge now and consent to lay domination of the practice of medicine.

That the Blue Cross plans to give medical service with or without the approval of the medical profession there can be no doubt after reading this report. The fact that the House of Delegates on numerous occasions has declared against the selling of medical service by hospitals has not stopped the practice. National approval or disapproval of any practice is a waste of time unless the state and county organizations will see that the dicta of the national body are carried out in the small localities.

The report gives the entire history of the whole matter and reviews the actions of previous House resolutions on the subject. It is high time that it was taken seriously not just for the duration of the meeting of the House but for the other 360 odd days of the year.

Your reference committee therefore recommends

A That the House emphatically reiterate that it disapproves the injecting of a third party into the personal relationship of the patient and the physician and that hospitals should not be permitted to practice medicine

B That the practice of radiology pathology and anesthesiology is the practice of medicine just as much as is the practice of surgery or internal medicine and that it is only a short step from including the first three in a medical service plan to including the whole field of medicine in such a plan

C That the public should be educated to realize that the hospital created monopoly control of radiologic or any service as a source of profit beyond the normal provision for replacement department development and proper proportion of over-all costs of operation of the hospital should not be permitted nor can the hospital rightfully use per diem charges against all the hospital patients to support a radiologic or other department devoted to creating bargains in radiologic or other services in order to make hospital group insurance more attractive. To permit either will result in decrease of the quality of service and increased cost to the patient.

D The medical profession must watch with care all proposed plans for medical service and endeavor to prevent the acceptance of any plan which includes medical service under the control of the hospital.

E The effectiveness of this program can be attained only if constituent state medical associations and component county medical societies use their influence on hospitals in their respective localities and exercise control over the local members of the medical profession.

F The public must be educated on what it will mean to them in the way of inferior medical care if these dangerous trends are not curbed.

G In the relationships of the medical staff and the board of directors of a hospital there should be no intermediary. The staff should have direct access to the board.

H The Board of Trustees should continue its conferences with national hospital associations and should also endeavor to

enlist the support of special medical organizations in education both of the profession and of the public.

The Board of Trustees in general and Dr. Sensenich and Dr. Irons in particular should be commended for the tremendous amount of time and effort which they have given in preparing their very informative report.

Your reference committee recommends that the House of Delegates of the American Medical Association urge the American Hospital Association to withhold approval of the uniform comprehensive Blue Cross contract proposed by the Hospital Service Plan Commission of the American Hospital Association which includes certain medical services as a part of hospital care and which it adopted as recommended by the said commission, would virtually compel the addition of medical services to the benefits of those Blue Cross plans and now accede to the demands of the American Medical Association by confining their benefits to hospital services.

26 Board of Trustees. Your reference committee is aware of frequent criticisms of the Board of Trustees because the Board does not do this or that and although it should be well known by the medical profession at large, it is worth repeating that the Board of Trustees is bound by the mandates of the House and the House is responsible for the Board's activities. Your reference committee feels that the House should express its appreciation of the tremendous amount of work carried on throughout the year by the Trustees, an amount of work which has been greatly increased by the war. It recommends therefore that the House express its heartfelt thanks to the members of the Board for their efficient work.

REPORT OF THE TREASURER

The report of the Treasurer has already been covered in substance in the section of the Report of the Board of Trustees under the heading of 'Income and Expenditures.'

Your reference committee recommends the approval of the report and notes with satisfaction the excellent financial status of the Association. Your reference committee also approves the appointment of Dr. Olin West as ad interim Treasurer following the resignation of Dr. Kretschmer. It feels that the House owes a debt of gratitude to Dr. Kretschmer for his untiring and faithful services as Treasurer for many years and so recommends.

Respectfully submitted

LOUIS H. BAUER, Chairman
W. A. COVENTRY
ANDREW F. MCBRIDE
JAMES R. McVAY

It was moved by Dr. Felix J. Underwood, Mississippi, duly seconded and carried that the House thank the reference committee for the excellent analysis and very complete report.

Report of Reference Committee on War Participation

Dr. Stanley H. Osborn, Chairman, presented the following report which was adopted on motions of Dr. Osborn, duly seconded and carried.

Your reference committee had referred to it that portion of the report of the Board of Trustees dealing with participation in the war effort contained in the report of the Board of Trustees as printed in the Handbook, pages 33 to 36 and the report of the 1942-1943 Committee on War Participation.

Your reference committee is in complete accord with the action of the Board of Trustees in making available to the Procurement and Assignment Service and to other federal services assistance, advisory services and such facilities of our Association as would be of value to the war effort.

Your reference committee commends the work of the Board of Trustees in authorizing the preparation and turning out of a scientific news letter to the officers of the medical departments of the armed forces and it compliments the editors of WAR MEDICINE and hopes that publication will continue along the same high standard so evident in the past.

Your reference committee approves the arrangements made by the War Participation Committee with the Surgeon General of the U. S. Public Health Service whereby the Public Health Service in conjunction with the Procurement and Assignment Service has undertaken studies of the medical needs in certain

June 4, 1942
Friday

critical areas of the country. It seems evident that only by collecting such factual data can the relative needs of the civilian population in the different areas be assessed.

Your reference committee approves in principle the development in the different states of plans whereby certain physicians from other states not acceptable to the armed forces may be allowed to practice in the duration of the war emergency in critical areas where the medical needs of the civilian population may be assisted by such action. These plans may be different in the several states and should be worked out by each constituent state medical association in accordance with its local problems. Your reference committee would emphasize the importance of such licensed physicians being accepted serving as bona fide citizens.

Your reference committee suggests that in those states where the Procurement and Assignment Service feels the need of a medical advisory group it request that a state war participation committee be appointed by the state medical society.

Your reference committee feels closer relations between the War Participation Committee and those in authority who during the war emergency are in control of medical education and training. It recommends the continuation of the War Participation Committee in order that it may continue to serve in the admirable way it has in assisting in the war effort and for civilian health in accordance with the report of the House of Delegates at the 1942 session.

NEW BUSINESS

Resolution Requesting Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education

Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, presented the following resolution which was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

WHEREAS Education is the hope of the world for better citizenship, patriotism, stability and understanding; and

WHEREAS Opportunity is knocking at the doors of our high schools to present the great achievements of medical progress in the last few decades, therefore be it

Resolved That the Board of Trustees prepare a concise statement of the achievements of the medical profession, especially the prevention of blindness and deafness, to be sent through the state medical societies to the boards of education in charge of high schools throughout the nation.

Resolutions Opposing Legislative Recognition of Cultists

Dr. J. F. Hassig, Kansas, presented the following resolutions which were referred to the Reference Committee on Medical Education.

WHEREAS The members of the Kansas Medical Society believe that the osteopathic, chiropractic and other cultist schools of the healing art are entirely unqualified for the adequate instruction of their students in the practice of medicine, surgery, obstetrics and any branches thereof; and

WHEREAS These cultists and their schools have arisen as healing methods opposed to the use of medicine and surgery; and

WHEREAS The licensed practitioners of these healing arts are in ever increasing numbers practicing medicine and surgery, often illegally; and

WHEREAS This is resulting in a lowering of the standards of medical practice in many states because of the admission in various degrees to the practice of medicine and surgery by the cultists, especially the osteopaths, whereby the osteopathic schools become in effect diploma mills for the practice of medicine and surgery; and

WHEREAS, The Kansas medical profession rejects the idea that any of the cultists are qualified to practice medicine and surgery, therefore be it

Resolved That the proper department of the American Medical Association be suitably expanded to acquire the material and develop suitable means to combat this evil of legislative recognition of the cultists to participate in the practice of medicine and surgery for which they are unqualified and be it further

Resolved That the House of Delegates of the Kansas Medical Society be requested to inform the American Medical Association of the above resolutions and be it further

Resolved That the resolutions be presented to the House of Delegates of the American Medical Association at its next meeting in Chicago.

Resolution on Amendment to the Federal Compensation Act

Dr. Edward C. Pogue, New York, introduced a resolution seeking to effect an amendment of the Federal Compensation Act. The resolution was referred without reading to the Reference Committee on Legislation and Public Relations.

Resolution Proposing Amendment to Constitution, Article 5, Section 3

Dr. Arthur S. Risser, Oklahoma, presented the following resolution proposing an amendment of the Constitution, Article 5, Section 3, which under the Constitution and By-Laws may be over for action and next year.

WHEREAS The American Medical Association is a national organization of physicians and surgeons and medical students; and

WHEREAS There is no one state association of physicians and surgeons and are organized in more or less similar manner in all states and territories and provinces and are different from those in other countries; and

Resolved That the House of Delegates of the American Medical Association be requested to propose to the following association of the Constitution of the American Medical Association.

Article 5, Section 3, of the Constitution of the American Medical Association.

After the adoption of this amendment, the House of Delegates will elect at the earliest possible time a committee of three Trustees from each of the Massachusetts River and all other members to all members of these Trustees shall be from states where the Medical Association has no members and at all times be retained.

On motion of Dr. E. H. Cary, Texas, seconded by Dr. Charles E. Morgan, Massachusetts, the House voted 12-05 p. m. for lurchion.

Tuesday Afternoon, June 8

The House of Delegates was called to order by the Speaker at 2:05 p. m.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Louis H. Bauer, Chairman, presented the following report which was adopted on motion of Dr. Bauer seconded by Dr. Arthur T. McCormack, Kentucky, and carried.

Resolution Requesting Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education. Your reference committee feels that this is a rather large order particularly with regard to preparing a statement on the achievements of the medical profession as a whole. However it is believed that a statement could be prepared and published in HYGIENIA which reaches all of the high schools in the country. In addition, as a possible motion pictures should be prepared for general release which could cover the prevention of deafness and blindness and highlight the achievements of the profession in the prevention of disease and the elements of public health in general.

Your reference committee so recommends and further recommends that the Section on Ophthalmology and on Laryngology, Otolaryngology and Rhinology be consulted in the preparation of the material.

Respectfully submitted

LOUIS H. BAUER, Chairman
ANDREW F. McBRIDE
W. A. COVENTRY
JAMES R. McVAY

On motion of Dr. Arthur T. McCormack, Kentucky, seconded by Dr. Walter E. Vest, West Virginia, and carried as amended, attendance at the Executive Session was granted to members of the House of Delegates, any alternate delegates in attendance, employees of the Association, full time secretaries of constituent state medical associations and component county or district medical societies, secretaries of regional medical associations, men of procurement and assignment committees for states.

are present officers of constituent state medical associations properly accredited, editors of medical journals the chairman of the committee on public health legislation of the Medical Society of the State of Pennsylvania and deans of medical schools

Executive Session—Tuesday Afternoon, June 8

The Sergeants-at-Arms polled the House after which on motion of Dr William R Brooksher Arkansas, seconded by Dr Arthur J Bedell, Section on Ophthalmology and carried the House went into Executive Session at 2 15 p m with Dr H H Shoulders, Speaker presiding

Report of Reference Committee on Legislation and Public Relations

Dr Thomas A McGoldrick Chairman presented the following report

1 Resolution Expressing Approval of Federal Assistance to Wives and Children of Service Men as Outlined in Plan Under Consideration by Federal Childrens Bureau, introduced by Dr John H Fitzgibbon Oregon Your reference committee recommends (a) that the action of the federal government in making funds available for maternity and infant care for the wives and infants of enlisted men be approved and (b) that adoption be urged of a plan under which the federal government will provide for the wives of enlisted men a stated allotment for medical hospital maternity and infant care similar to the allotments already provided for the maintenance of dependents leaving the actual arrangements with respect to fees to be fixed by mutual agreement with the wife and the physician of her choice

2 Resolution Approving Proposed Changes in Regard to Medical Services of the American Red Cross in Disaster Relief submitted by Dr Arthur T McCormack Kentucky Your reference committee recommends that this resolution be approved

3 Resolution Urging the Creation of a Federal Department of Health introduced by Dr Thomas A McGoldrick in behalf of the New York State delegates Your reference committee recommends the adoption of this resolution with the insertion of the words which shall have full responsibility for all the medical and health activities of the government with the exception of those connected with the armed forces so that the resolution will now read

Resolved That the American Medical Association urge with all the power at its command that a federal department of Health be created which shall have full responsibility for all the medical and health activities of the government with the exception of those connected with the armed forces and that this department be headed by a Secretary of Health who shall be a properly qualified Doctor of Medicine and who is a member of a component county medical society

4 Resolution Requesting Changes in Administration of Federal Security Law so as to Assure Payment of the Physician introduced by Dr Walter P Anderton New York Your reference committee recommends that this resolution be disapproved because it involves the introduction of a third party a party coming between the patient and the physician Such practice has already been disapproved by the American Medical Associations House of Delegates

5 Report of Bureau of Legal Medicine and Legislation in Report of Board of Trustees contained in Handbook pages 77-107 Your reference committee commends the Board of Trustees on that part of its report covering the activities of the Bureau of Legal Medicine and Legislation Particular attention is called to the study given medical licensure and the war and the model code of evidence adopted by the American Law Institute in which suggestions of the Bureau regarding the physician-patient relationship were included

Your reference committee calls to your attention the large amount of work done by this bureau and is of the opinion that its activities could be further increased to the ultimate good of the medical profession

6 Resolutions Dealing with the Creation of a Council or Committee on Medical Service and the Establishment of an

Office of the American Medical Association in Washington D C introduced by Drs W A Coventry Minnesota F S Crockett Indiana Wells P Eagleton New Jersey Karl S J Hohlen Nebraska, Arthur S Risser Oklahoma and Barney J Hunt Ohio All these resolutions as well as the opinions expressed at the open meeting of your reference committee have been given full earnest consideration There appears one objective in all of them Therefore your reference committee respectfully submits the following recommendation A Council on Legal Medicine and Legislation shall be created at once this Council to be composed of six members of the American Medical Association geographically distributed over the United States the President the Secretary the immediate Past President and a member of the Board of Trustees of the American Medical Association The six members from the American Medical Association for the first year shall be appointed by the Board of Trustees Your reference committee recommends that the term of membership on the Council be three years provided that at the end of the first year there be an election of two members for one year two for two years and two for three years After the first year the Board of Trustees shall present to the House of Delegates for election to membership on this Council a list of three nominees for each vacancy and the Chairman shall be selected by the Council from its elected members

The duties of this Council shall be to make available all facts data and medical opinions with respect to timely and adequate rendition of medical care to the American people and to keep informed the constituent state medical associations and component county medical societies of all proposed changes affecting medical care in the nation and also the activities of the Council The present Bureau of Legal Medicine and Legislation shall be made a part of this Council and the Board of Trustees shall provide adequate facilities for these activities

Respectfully submitted

THOMAS A MCGOLDRICK Chairman
EDWIN S HAMILTON
LLOYD NOLAND
PARKE G SMITH
WILLIAM R MORONY SR

The first section of the report referring to the Resolutions Expressing Approval of Federal Assistance to Wives and Children of Service Men as Outlined in Plan Under Consideration

1 The resolution as introduced by Dr Eagleton on June 7 1943 was not published in full in THE JOURNAL last week The resolution should read as follows

RESOLUTION REQUESTING ESTABLISHMENT OF A LEGISLATIVE BUREAU OF THE AMERICAN MEDICAL ASSOCIATION IN WASHINGTON

With respect to the recommendation about to be introduced on behalf of the New Jersey delegation we should mention that immediately following the annual meeting of the Medical Society of New Jersey held May 25 and 26 and pursuant to a resolution adopted at this meeting a letter from the secretary of our society containing the resolution regarding the establishment of a legislative bureau of the Association in Washington together with a brief in support of this proposal was sent to all of the listed Delegates of the Association and since our arrival we have attempted to place in the hands of the other Delegates the material referred to

We shall reserve further arguments in support of this proposal for the hearing before the reference committee but we should like to emphasize that in making this recommendation it is not to be assumed that this in any way is a reflection on the Bureau of Legal Medicine and Legislation We believe from our experience and our relations with this Bureau that it is doing an excellent job within the setup now existing The Legislative Committee of the Medical Society of New Jersey is particularly appreciative of the fine cooperation given by the Director of the Bureau Mr Holloway in relation to some of our state problems and has a high regard for his ability and judgment

In reiterating this recommendation we should appreciate it if the Speaker will permit these remarks to be attached

WHEREAS It is increasingly apparent in view of the present trend as signally demonstrated by the introduction of bills in the Congress only last Thursday (June 3) to establish an American Beveridge Plan of Social Security and as evidenced by the growing number and variety of measures being proposed in the Congress affecting public health and medical practice that it is impossible for the Association without representation in Washington to present the opinion of the organized medical profession properly and adequately on these measures to the members and committees of the Congress and to the public especially to the organized groups of labor agriculture industry and veterans and to keep the component societies of the American Medical Association fully and promptly informed therefore be it

Resolved That to accomplish these and related purposes the House of Delegates requests the Board of Trustees of the Association to establish promptly a legislative bureau in Washington this bureau to be under the direction of the Bureau of Legal Medicine and Legislation

by Federal Children's Bureau, was adopted on motion of Dr McGoldrick, seconded by Dr James Q Graves, Louisiana, and carried after discussion by Dr Holman Taylor, Texas, and Dr McGoldrick.

Dr McGoldrick moved the adoption of the second section of the report of the reference committee, approving the Resolution Approving Proposed Changes in Regard to Medical Services of the American Red Cross in Disaster Relief. The motion was seconded by Dr Arthur I McCormack, Kentucky, and carried.

The substitute resolution suggested in the third section of the report of the reference committee was adopted instead of the Resolution Urging the Creation of a Federal Department of Health as introduced by Dr Thomas A McGoldrick, New York, on motion of Dr McGoldrick, seconded by Dr Charles E Mongan, Massachusetts, and carried.

The fourth section of the report of the reference committee recommending the disapproval of the Resolution Requesting Changes in Administration of Federal Security Law so as to Assure Payment of the Physician was adopted on motion of Dr McGoldrick, seconded by Dr Arthur J Bedell, Section on Ophthalmology, and carried.

Section 5 of the report of the reference committee, commending the report of the Board of Trustees covering the activities of the Bureau of Legal Medicine and Legislation, was adopted on motion of Dr McGoldrick, seconded by Dr Arthur T McCormack, Kentucky, and carried after discussion by Drs Olin West, Secretary, Arthur J Bedell, Section on Ophthalmology, R W Fouts, Vice Speaker, G Henry Mundt, Illinois, the Speaker and Dr McGoldrick.

Dr McGoldrick moved that the sixth section of the report of the reference committee, recommending the establishment of a Council on Legal Medicine and Legislation, be adopted. The motion was seconded by Dr James R Reuling Jr, New York. There was discussion by Drs Wells P Eagleton, New Jersey, James C Sargent, Wisconsin, Walter E Vest, West Virginia, A W Adson, Minnesota, and Barney J Hein, Ohio, who offered the following amendment to the report of the reference committee: "The Board of Trustees is hereby directed to provide adequate funds for such council to maintain a permanent office, properly equipped and with adequate personnel, in our National Capital, in order that our membership can be more quickly informed of the legislative developments which concern the practice of medicine, so the public can be rendered better medical and health services."

Dr William M Skipp, Ohio, moved the adoption of the amendment, and the motion was seconded by Dr Charles R Meek, Ohio, and was discussed by Dr Allen H Bunce, Georgia, Speaker H H Shoulders, Dr McGoldrick, and Dr Walter B Martin, Virginia. Dr A A Walker, Alabama, moved that the amendment be tabled. The motion to table was carried by a rising vote of 114 for it to 21 against it.

After further discussion on the adoption of the sixth section of the report of the reference committee by Drs Louis H Bauer, New York, H H Shoulders, Speaker, and Walter B Martin, Virginia, and Dr McGoldrick, the motion to adopt the sixth section of the report of the reference committee carried and that section of the report was adopted.

On motion of Dr McGoldrick, seconded by Dr A A Walker, Alabama, and carried, the report of the reference committee was adopted as a whole.

The Speaker took the liberty of extending an expression of appreciation to the reference committee, and referred the report to the Board of Trustees.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr Walter E Vest, Chairman, presented the following report:

Resolutions Requesting the Establishment of a Council on Medical Care. Your reference committee has carefully considered the resolution offered by Dr Skinner, Section on Radi-

ology, to amend the Constitution and By-Laws in order to create a Council on Medical Care. It recognizes the merit in the proposal and realizes fully the desirability of establishing such a council.

It recommends, therefore, that the first five paragraphs of the resolution be adopted and that the Board of Trustees be empowered to establish such a council as soon as feasible. Your reference committee recommends, therefore, that this council, when established, be named the Council on Medical Service rather than on Medical Care.

Inasmuch as the subject matter of paragraph 6 is covered by a number of resolutions referred to the Committee on Legislation and Public Relations, your reference committee deems it wise to offer no report on this paragraph.

Respectfully submitted,

WALTER E VEST, Chairman
ELBERT G WOOD
LOUIS A BUIE
KARL S J HOHLEN
WILLIAM WESTON

It was moved by Dr Arthur T McCormack, Kentucky, that this be referred to the Board of Trustees. The motion was seconded by Dr James R Miller, Connecticut, and carried after discussion by Drs Arthur J Bedell, Section on Ophthalmology, Edward H Cary, Texas, E H Skinner, Section on Radiology, Arthur T McCormack, Kentucky, Holman Taylor, Texas, Thomas A McGoldrick, New York, H H Shoulders, Speaker, Walter E Vest, West Virginia, Olin West Secretary, and Henry C Macatee, District of Columbia.

It was moved by Dr Louis H Bauer, New York, seconded by Dr Robert E Schlueter, Missouri, and carried, that the Board of Trustees be asked to take into consideration the various boards existing and just established and bring in some clarifying statement as to the status of all of them and, if necessary, recommend reconsideration of some of the actions taken today.

It was moved by Dr R W Fouts, Vice Speaker, that the House rise from Executive Session and continue with the regular business. The motion was seconded by Dr William R Brooksher, Arkansas, and carried, and the House rose from Executive Session at 3 45 p m.

Tuesday Afternoon—Continued

The House reconvened in regular session at 3 45 p m with Dr H H Shoulders, Speaker, presiding.

Report of Reference Committee on Medical Education

Dr Wilbur C Davison, Chairman, presented the following report, in which the Reference Committee on Medical Education recommended that the Resolutions Opposing Legislative Recognition of Cultists introduced by Dr J F Hassig, Kansas, be referred to the Board of Trustees.

In regard to these resolutions of the Kansas Medical Society, the objects of the American Medical Association are to promote the science and art of medicine and the betterment of public health. The Council on Medical Education and Hospitals believes that only graduates in medicine of approved medical schools should be licensed in the practice of medicine and the healing art. In view of the fact that the various states have legislative acts permitting the licensure of others than graduates of approved medical schools, the purpose of the resolutions of the Kansas Medical Society is beyond the functions and scope of the Council on Medical Education and Hospitals. At the present time there is being conducted a survey of seven osteopathic schools for purposes of comparison with seven approved medical schools in similar areas and further action on these resolutions should await the publication of the findings of this survey of the National Research Council.

It is therefore recommended by your reference committee that these resolutions be submitted to the Board of Trustees.

On motion of Dr Davison, seconded by Dr James Q Graves, Louisiana, the report of the reference committee was adopted.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Arthur T. McCormack, Kentucky, and carried after amendment the House recessed at 3:50 p. m. to reconvene at 10 a. m. Wednesday, June 9.

Third Meeting—Wednesday Morning, June 9

The House of Delegates was called to order at 10 a. m. by the Speaker Dr. H. H. Shoulders.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that a total of 170 delegates had been seated and added that he wished to repeat that all constituent state associations and all sections were fully represented and that the only delegates not in attendance are those representing Alaska, the Isthmian Canal Zone, the Philippines and Puerto Rico.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of Minutes

On motion of Dr. Arthur T. McCormack, Kentucky, seconded by Dr. H. B. Everett, Tennessee, and carried the House dispensed with the reading of the minutes.

Report of Board of Trustees

Dr. Roger I. Lee, Chairman, stated that the Board of Trustees met with the members of the Reference Committee on Legislation and Public Relations and of the Reference Committee on Amendments to the Constitution and By-Laws and the Board of Trustees took action as follows:

On motion duly seconded and carried the Board of Trustees proposed the formation of a Council on Medical Service and Public Relations to be composed of six members of the American Medical Association geographically distributed over the United States with the President, the immediate Past President, the Secretary and a member of the Board of Trustees of the American Medical Association. For the first year the six members shall be appointed by the Board of Trustees. The term of membership of the Council shall be three years provided that at the end of the first year there shall be an election of two members for one year, two for two years and two for three years. After the first year the Board of Trustees shall present to the House of Delegates for election to membership on this Council a list of three nominees for each vacancy. The Chairman shall be selected by the Council from its elected members. The duties of the Council shall be:

(a) To make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people; (b) to inform the constituent associations and component societies of proposed changes affecting medical care in the nation; (c) to inform constituent associations and component societies regarding the activities of the Council; (d) to investigate matters pertaining to the economic, social and similar aspects of medical care for all the people; (e) to study and suggest means for the distribution of medical services to the public consistent with the principles adopted by the House of Delegates; and (f) to develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association.

In the exercise of its functions this Council, with the cooperation of the Board of Trustees, shall utilize the functions and personnel of the Bureau of Legal Medicine and Legislation, the Bureau of Medical Economics and the Department of Public Relations in the headquarters office.

The Board of Trustees shall provide adequate facilities for these activities and shall prepare necessary changes in the By-Laws to accommodate the purpose of this resolution.

The Board also voted to propose that the present Committee on Legislative Activities of the House of Delegates be discharged with a vote of thanks for its work.

Dr. Lee then presented the following suggestions:

The following changes and additions in the By-Laws are suggested by the establishment of a Council on Medical Service and Public Relations:

Add to chapter VII, section 3, "(d) Council on Medical Service and Public Relations."

Insert "of these" between "each" and "Council" in the third sentence of section 1 of chapter VIII, making it read:

"The term of office of the members of each of these Councils shall terminate in succession, one each year," etc.

Add to section 1 of chapter VIII a new paragraph, reading as follows: "The Council on Medical Service and Public Relations shall include six members of the American Medical Association selected according to geographic distribution with the President, the immediate Past President, the Secretary and a member of the Board of Trustees. For the first year the six members shall be appointed by the Board of Trustees. The term of membership of the Council shall be three years provided that at the end of the first year there shall be an election of two members for one year, two for two years and two for three years. After the first year the Board of Trustees shall present to the House of Delegates for election to membership on this Council a list of three nominations for each vacancy. The Chairman shall be selected by the Council from its elected members."

Change the second part of section 2, chapter VIII, to read "and that on nomination by the respective Councils the Board of Trustees shall elect annually to serve one year, a secretary of the Council on Medical Education and Hospitals and a secretary of the Council on Medical Service and Public Relations, and shall fix their salaries (As amended, 1943)."

Add a new section to chapter IX as follows: "SEC. 4. COUNCIL ON MEDICAL SERVICE AND PUBLIC RELATIONS.—The functions of the Council on Medical Service and Public Relations shall be: (1) to make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people; (2) to inform constituent associations and component societies of proposed changes affecting medical care in the nation; (3) to inform constituent associations and component societies regarding the activities of the Council; (4) to investigate matters pertaining to the economic, social and similar aspects of medical care for all the people; (5) to study and suggest means for the distribution of medical service to the public consistent with the principles adopted by the House of Delegates; (6) to develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association."

In the exercise of its functions this Council, with the cooperation of the Board of Trustees, shall utilize the functions and personnel of the Bureau of Legal Medicine and Legislation, the Bureau of Medical Economics and the Department of Public Relations in the headquarters office.

Dr. George W. Kosmak, New York, moved the adoption of the report of the Board of Trustees. The motion was seconded by Drs. Francis F. Borzell, Pennsylvania, Arthur S. Risser, Oklahoma, F. S. Crockett, Indiana, James C. Sargent, Wisconsin, and A. W. Adson, Minnesota, and carried.

It was moved by Dr. Arthur T. McCormack, Kentucky, seconded by Dr. H. B. Everett, Tennessee, and carried that the amendments to the By-Laws contained in the report of the Board of Trustees be adopted.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas A. McGoldrick, Chairman, presented the following report:

1. Your reference committee, in possession of the facts relating to the By-Laws and their adoption by the House of Delegates, would implement and extend its report adopted yesterday by the statements in the report of the Board of Trustees, so that it will now read:

Your reference committee recommends the formation of a Council on Medical Service and Public Relations to be composed of six members of the American Medical Association geographically distributed over the United States, with the President, the immediate Past President, the Secretary and a member of the Board of Trustees of the American Medical Association. For the first year the six members shall be appointed by the Board of Trustees. The term of membership of the Council shall be three years provided that at the end of the first year there shall be an election of two members for one year, two for two years and two for three years. After the first year the Board of Trustees shall present to the House of Delegates for election to membership on this Council a list of three nominees for each vacancy. The Chairman shall be selected by the Council from its elected members. The duties of the Council shall be:

(a) to make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people, (b) to inform the constituent associations and component societies of proposed changes affecting medical care in the nation, (c) to inform constituent associations and component societies regarding the activities of the Council, (d) to investigate matters pertaining to the economic, social and similar aspects of medical care for all the people, (e) to study and suggest means for the distribution of medical services to the public consistent with the principles adopted by the House of Delegates, and (f) to develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association.

In the exercise of its functions this Council, with the cooperation of the Board of Trustees shall utilize the functions and personnel of the Bureau of Legal Medicine and Legislation, the Bureau of Medical Economics and the Department of Public Relations in the headquarters office.

The Board of Trustees shall provide adequate facilities for these activities and shall prepare necessary changes in the By-Laws to accommodate the purpose of this report.

2. Resolution on Amendment to the Federal Compensation Act, introduced by Dr. Edward C. Podvin, New York. Your reference committee approves this resolution.

Dr. McGoldrick moved the adoption of the first section of the report of the reference committee as the report of the committee on that subject, and the motion was seconded by Dr. Felix J. Underwood, Mississippi.

Dr. Arthur T. McCormack, Kentucky, moved that the House reconsider the vote by which this section of the report of the reference committee was adopted on yesterday, and the motion was seconded by Dr. Walter E. Vest, West Virginia, and carried, after discussion by Drs. Lowell S. Goun, California, Louis H. Bauer, New York, Louis A. Buie, Section on Gastro-Enterology and Proctology, William Weston, Section on Pediatrics, R. W. Fouts, Vice Speaker, and H. H. Shoulders, Speaker, and Dr. McCormack.

Dr. R. W. Fouts, Vice Speaker, moved to table the section of the report of the reference committee adopted on yesterday. The motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology.

On motion of Dr. Louis H. Bauer, New York, seconded by Drs. Arthur S. Rissei, Oklahoma, and Walter E. Vest, West Virginia, and carried, the report of the reference committee as just presented was substituted for the sixth section of the report of that committee presented on yesterday.

It was moved by Dr. McGoldrick that the report of the reference committee as just presented be adopted, and the motion was seconded by Drs. Walter E. Vest, West Virginia, and James Q. Graves, Louisiana, and carried.

Dr. McGoldrick moved the adoption of the second section of the report of the reference committee approving the resolution introduced by Dr. Edward C. Podvin, New York. The motion was seconded by Dr. John Z. Brown, Utah, and carried.

Dr. McGoldrick moved that the Committee on Legislative Activities be discharged as recommended by the Board of Trustees. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, and carried, and the Committee on Legislative Activities was discharged with the thanks of the House of Delegates.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Walter E. Vest, Chairman, stated that the matter the reference committee had under consideration had already been attended to in the report of the Reference Committee on Legislation and Public Relations.

Report of Reference Committee on Reapportionment

Dr. Arthur T. McCormack, Chairman, stated that the states unlike report of the Reference Committee on Amendments to the Constitution and By-Laws on yesterday disposed of the question of reapportionment and that there would be no report from the reapportionment committee, which would like to be discharged. Doubt as to that procedure was expressed because it is necessary to reapportion delegates every third year and this is the year for that purpose.

Dr. McCormack then stated that the reference committee reports progress.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the report of the reference committee be referred back to the committee with the request that it bring in a report. The motion was seconded and carried after discussion by Drs. Arthur T. McCormack, Chairman of the reference committee, H. H. Shoulders, Speaker, Olin West, Secretary, and Walter E. Vest, West Virginia, and Dr. Bedell.

On motion of Dr. Louis H. Bauer, New York, seconded and carried, the House recessed from 10:50 a. m. until 11 a. m.

Report of Reference Committee on Reapportionment

Dr. Arthur T. McCormack, Chairman, presented the following report which was adopted on motion of Dr. McCormack, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

Your reference committee has made a study of this matter and recommends that the basis of the apportionment of delegates for the next three years be one delegate for each 965 members or fraction thereof, each constituent association being represented by at least one delegate irrespective of the number of members.

The By-Laws specifically provide that the total membership of the House of Delegates shall not exceed 175. The total membership of the Association on April 1, 1943, as recorded in the office of the Secretary, was 122,741.

On the basis of one delegate for each 965 members or fraction thereof, the total membership of the House will be 175. On this basis Connecticut, New York and Ohio will each gain a delegate and Kentucky, North Carolina and South Carolina will each lose a delegate.

The Speaker expressed to the members of the reference committee a word of thanks for the very excellent work they have performed at this session of the House.

ELECTION OF OFFICERS

The Speaker declared the next order of business to be the election of officers.

Election of President-Elect

Dr. Charles H. Phifer, Illinois, nominated for President Elect Dr. Herman L. Kretschmer, Chicago, and the nomination was seconded by Drs. Arthur T. McCormack, Kentucky, James C. Sargent, Wisconsin, Allen H. Bunce, Georgia, Edward H. Cary, Texas, George W. Kosmak and Thomas A. McGoldrick, New York, Carl R. Steinke, Ohio, James Q. Graves, Louisiana, Walter E. Vest, West Virginia, Robert L. Anderson, Pennsylvania, Arthur J. Bedell, Section on Ophthalmology, and William R. Molony Sr., California, the five delegates.

from Michigan is well as the delegates from Kansas, Minnesota, Missouri, New Jersey and Pennsylvania. Dr. Elbert G. Wood, Tennessee, the delegates from Iowa, Dr. James P. Wall, Mississippi, Dr. Roy B. Henline, Section on Urology, the delegates from Massachusetts and Dr. Grover C. Penberthy, Section on Surgery, General and Abdominal.

Membership of House of Delegates

* From records last received

On motion of Dr. A. A. Walker, Alabama, seconded by Dr. Louis H. Bauer, New York, and carried, the nominations were closed.

It was moved by Dr. Arthur T. McCormack, Kentucky, that the Secretary be instructed to cast the ballot of the House for Dr. Herman L. Kretschmer for President-Elect, and the motion was seconded by several delegates and carried.

The Secretary cast the ballot of the House of Delegates for Dr. Herman L. Kretschmer, Chicago, for President-Elect of the American Medical Association for the ensuing year, and the Speaker declared Dr. Kretschmer so elected.

Election of Vice President

Dr. Walter F. Donaldson, Pennsylvania, nominated Dr. Edward L. Bortz, Philadelphia, and the nomination was seconded by Drs. H. B. Everett, Tennessee, Clyde L. Cummer, Section on Dermatology and Syphilology, William Weston, Section on Pediatrics and Robert H. Hayes, Illinois.

Dr. Walter W. King, Colorado, nominated Dr. John W. Amesse, Denver, and the nomination was seconded by delegates from Wyoming, Illinois, Arkansas, Louisiana and Minnesota. Dr. Arthur S. Risser, Oklahoma, Dr. E. N. Roberts, Idaho, Dr. Grover C. Penberthy, Section on Surgery, General and Abdominal, Dr. James R. McVay, Missouri, Dr. E. H. Skinner, Section on Radiology, and Dr. John Z. Brown, Utah.

On motion of Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the nominations were closed and the tellers spread the ballot.

The Secretary announced that 155 votes had been cast out of a registration present of 158 of which Dr. Bortz received 54 and Dr. Amesse 101, and the Speaker declared Dr. Amesse elected Vice President of the American Medical Association for the ensuing year.

On motion of Dr. Walter F. Donaldson, Pennsylvania, seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and carried, the election of Dr. Amesse was declared unanimous.

Introduction and Address of Dr. Herman L. Kretschmer

Dr. Charles H. Phifer, Illinois, presented the new President-Elect, Dr. Herman L. Kretschmer, Chicago, who addressed the House as follows:

Mr. President, Mr. Speaker, Members of the House of Delegates of the American Medical Association: May I thank you from the bottom of my heart for electing me to this high office of President-Elect of the American Medical Association? I feel that this is the highest honor that can be paid to a member of the American Medical Association.

I am mindful of the fact that this honor carries with it many obligations and you who represent more than 123,000 doctors in the United States I hope will find your confidence in me has not been misplaced.

You have had a long trying session. I will not burden you with a long speech. I wish to take this opportunity to thank the House for the privilege it has given me to serve you as your Treasurer for ten years. I cannot let this opportunity go by without thanking the Board of Trustees. Since I began sitting in with its members ten years ago the complexion of the Board has changed completely and there are not on that Board today any of the original men who were on the Board in 1933. Irrespective of the change in personnel in this Board I wish all of you knew how honestly and sincerely and how conscientiously the Board performs its work. It turns over many of the problems that you present to it with great deliberation, having always in mind what is best for American medicine.

And last but not least I wish to pay my respects to and to thank Dr. Olin West, whom somebody called yesterday the great grand man of American medicine. He has always been most cooperative, he has always been most helpful, and it was a joy and a privilege to work with him.

Again my sincerest thanks to the members of the House for electing me to this exalted position. I thank you.

Election of Secretary

Dr. E. E. Barlow, Arkansas, nominated Dr. Olin West, Chicago, to succeed himself as Secretary of the American Medical Association and the nomination was seconded by Drs. William Weston, Section on Pediatrics, Robert A. Peers, Cal-

formal, Wells P Eagleton, New Jersey, George M Kosmak, New York, Stephen E Gavin, Wisconsin, James Q Graves, Louisiana, Walter W King, Colorado, Henry Cook Macatee, District of Columbia, H B Everett, Tennessee, Thomas A McGoldrick, New York, Walter E Vest, West Virginia, Olin H Weaver, Georgia, William A Muller, Georgia, Felix J Underwood, Mississippi, George P Johnston, Wyoming, E H Cary, Texas, Mather Pfeifferberger, Illinois, Burt R Shurly, Section on Laryngology, Otology and Rhinology, J F Hassig, Kansas, Robert F Schlueter, Missouri, Charles L Mongan, Massachusetts, W A Coventry, Minnesota, Frank E Reeder, Michigan, F S Crockett, Indiana, John H Fitzgibbon, Oregon, Ivan Fawcett, West Virginia, John Z Brown, Utah, Forrest J Pinkerton, Hawaii, Virgil E Simpson, Kentucky, Deering G Smith, New Hampshire, N J Nessa, South Dakota, Louis H Bauer, New York, Francis F Borzell, Pennsylvania, and several other delegates from Pennsylvania, Indiana and Delaware.

Dr William Weston, Section on Pediatrics, moved that the nominations be closed, and the motion was seconded by Dr James Q Graves, Louisiana, and carried.

On motion of Dr Arthur J Bedell, Section on Ophthalmology, seconded by Dr Wells P Eagleton, New Jersey, and carried, the Speaker of the House cast the ballot of the House for Dr Weston Secretary for the ensuing year and declared Dr Weston so elected.

Election of Treasurer

Dr Roger I Lee, Chairman in behalf of the Board of Trustees, placed in nomination for Treasurer of the American Medical Association Dr Josiah J Moore, Chicago. The nomination was confirmed on motion of Dr James Q Graves, Louisiana seconded by Dr Edwin S Hamilton, Illinois, and carried. The Speaker declared Dr Josiah J Moore, Chicago, elected Treasurer of the American Medical Association for the ensuing year.

Election of Speaker of House of Delegates

With Dr R W Fouts, Vice Speaker, in the chair, Dr H B Everett, Tennessee, nominated Dr H H Shoulders, Nashville, Tenn, to succeed himself as Speaker of the House of Delegates of the American Medical Association, and the nomination was seconded by Drs James Q Graves and Leon J Menville, Louisiana, Arthur T McCormack, Kentucky, Louis A Buie, Section on Gastro-Enterology and Proctology, Burt R Shurly, Section on Laryngology, Otology and Rhinology, Wells P Eagleton, New Jersey, J F Hassig, Kansas, Frank E Reeder, Michigan, and delegates from Illinois. The nominations were closed on motion of Dr Louis A Buie, Section on Gastro-Enterology and Proctology, seconded by Dr George P Johnston, Wyoming, and carried.

On motion of Dr Arthur T McCormack, Kentucky, seconded by Dr James Q Graves, Louisiana, and carried, the Secretary cast the ballot of the House for Dr H H Shoulders, Nashville, Tenn, for Speaker of the House of Delegates of the American Medical Association for the ensuing year and the Vice Speaker declared Dr Shoulders so elected.

Election of Vice Speaker of House of Delegates

The Speaker resumed the chair and called for nominations for Vice Speaker of the House of Delegates.

Dr A W Adson, Minnesota, nominated for Vice Speaker of the House of Delegates of the American Medical Association Dr R W Fouts, Omaha. The nomination was seconded by Drs James Q Graves, Louisiana, Edwin S Hamilton, Illinois, Stephen E Gavin, Wisconsin, Walter W King, Colorado, and Robert E Schlueter, Missouri. On motion of Dr James Q Graves, Louisiana, seconded by Dr Roy B Henline, Section on Urology, and carried, the nominations were closed.

Dr E G Wood, Tennessee, moved that the Speaker cast the ballot of the House for Dr Fouts to succeed himself as Vice Speaker of the House of Delegates. The motion was seconded by Dr James Q Graves, Louisiana, and carried. The Speaker cast the ballot of the House for Dr R W Fouts,

Omaha, to succeed himself as Vice Speaker of the House of Delegates of the American Medical Association for the ensuing year and declared Dr Fouts so elected.

Election of Trustees

Dr Arthur T McCormack, Kentucky, nominated Dr William F Braasch, Rochester, Minn, to succeed himself as a member of the Board of Trustees for a term of five years. The nomination was seconded by Drs A W Adson, Minnesota, E H Cary, Texas, Louis A Buie, Section on Gastro-Enterology and Proctology, Stephen E Gavin, Wisconsin, Thomas A McGoldrick, New York, James M Hayes, Minnesota, James R McVay, Missouri, R K Packard, Illinois, F S Crockett, Indiana, and Robert E Schlueter, Missouri. On motion of Dr James Q Graves, Louisiana, seconded by Dr Arthur J Bedell, Section on Ophthalmology, and carried, the nominations were closed.

It was moved by Dr Arthur T McCormack, Kentucky, seconded and carried, that the Secretary cast the ballot of the House for Dr William F Braasch to succeed himself for a term of five years as a member of the Board of Trustees of the American Medical Association, and the Speaker declared Dr Braasch so elected, after the Secretary cast the ballot.

Dr G Henry Mundt, Illinois, nominated as a member of the Board of Trustees to succeed himself for a term of five years Dr Ernest E Irons, Chicago. The nomination was seconded by Drs Thomas P Murdock, Connecticut, Clyde L Cummer, Section on Dermatology and Syphilology, Thomas A McGoldrick, New York, George P Johnston, Wyoming, Deering G Smith, New Hampshire, Felix J Underwood, Mississippi, Robert E Schlueter, Missouri, and Olin H Weaver, Georgia. A motion by Dr Olin H Weaver, Georgia, seconded by Dr Sam E Thompson, Texas, to close the nominations was carried.

The Secretary cast the ballot of the House for Dr Ernest E Irons, Chicago, to succeed himself as a member of the Board of Trustees of the American Medical Association for a term of five years, on motion of Dr Clyde L Cummer, Section on Dermatology and Syphilology, seconded by Dr James Q Graves, Louisiana, and carried, and the Speaker declared Dr Irons so elected.

Nomination for Standing Committees

NOMINATIONS BY DR JAMES E PAULLIN, PRESIDENT

Dr James E Paullin, President nominated Dr John H O'Shea, Spokane, Wash, to succeed himself as a member of the Judicial Council for a term of five years.

On motion of Dr Arthur T McCormack, Kentucky, seconded by Dr Felix J Underwood, Mississippi, and carried, the nomination of Dr O'Shea was confirmed.

Dr Paullin nominated Dr Edward L Bortz, Philadelphia, to succeed himself as a member of the Council on Scientific Assembly for a term of five years.

On motion of Dr Walter F Donaldson, Pennsylvania, seconded by Dr Clyde L Cummer, Section on Dermatology and Syphilology, and carried, the nomination of Dr Bortz was confirmed.

NOMINATION BY THE BOARD OF TRUSTEES

Dr Roger I Lee, Chairman, stated that the Board of Trustees wished to nominate Dr Russell L Haden, Cleveland, to succeed himself as a member of the Council on Medical Education and Hospitals for a term of seven years.

The nomination of Dr Haden was confirmed on motion of Dr Barney J Hen, Ohio, seconded by Dr Walter E Vest, West Virginia, and carried.

Election of Affiliate and Associate Fellows

NOMINATIONS FOR AFFILIATE FELLOWSHIPS APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

The Secretary presented the following nominations for Affiliate Fellowship, properly approved by the Council on Scientific

Assembly, which, on motion of Dr Arthur J Bedell, Section on Ophthalmology, seconded by Dr James C Stargent, Wisconsin, and carried, were confirmed

Abbot E Stanley Wyland Mrs	Fibby J H E Weymouth Mass

Place of 1946 Annual Session

Dr Roger I Lee Chairman, Board of Trustees, presented the following statement

The Board of Trustees received no invitations up to this morning but during the morning an invitation was received as follows

The California Medical Association takes pleasure in extending to the American Medical Association an invitation to hold its 1946 convention in the city of San Francisco

We look forward to a convention held in a time of victorious place in which there can be shown the part medicine played in winning the war

Cordially yours,

LOWELL S GOIN, President-Elect,
and Delegate to American Medical Association
DWIGHT L WILBUR, Delegate
LYELL C KINNEY, Delegate
HENRY S ROGERS, Delegate
EDWARD N EWER, Delegate
WILLIAM H KIGER, Delegate
ROBERT A PEERS, Delegate
WILLIAM R MOLOVY SR, Delegate"

On motion of Dr Arthur J Bedell, Section on Ophthalmology, seconded by Dr John Z Brown, Utah, and Dr Felix J Underwood, Mississippi, and carried, the House voted that the 1946 session of the American Medical Association shall be held in San Francisco. The Speaker declared San Francisco the place of the 1946 annual session of the American Medical Association

Expressions of Appreciation

NOTE OF THANKS TO SPEAKER

With the Vice Speaker in the Chair, a vote of thanks to the Speaker for his very efficient and splendid service was extended on motion of Dr Burt R Shurly, Section on Laryngology, Otology and Rhinology, seconded by Dr Arthur J Bedell, Section on Ophthalmology and carried

The Speaker resumed the Chair

EXPRESSION OF APPRECIATION TO THE NATIONAL BROADCASTING COMPANY

It was moved by Dr Arthur T McCormack, Kentucky, seconded by Dr Felix J Underwood, Mississippi and carried, that the House express itself as being grateful to the National Broadcasting Company for its cooperation in making the broadcasting program of the American Medical Association possible

EXPRESSION OF APPRECIATION TO BRIG GEN FRED W RANKIN

Dr Arthur T McCormack, Kentucky, moved that the House of Delegates express to the retiring President Brig Gen Fred W Rankin its gratitude for the very arduous service he has rendered along with his responsibilities in the Army and wish him good in war and in peace. The motion was seconded by Drs Clyde L Cummer, Section on Dermatology and Syphilology, Felix J Underwood Mississippi and Wells P Eagleton, New Jersey, and carried

Telegram from President of Southern Medical Association

Dr Felix J Underwood, Mississippi, presented the following telegram which was ordered filed in the records of the American Medical Association

In your deliberations in behalf of the nation's health and the promotion of our war efforts may I convey to the officers and the members of the House of Delegates of the greatest medical association in the world the fullest cooperation and greetings from the Southern Medical Association. Love to all Harvey F Garrison"

Response of Brig Gen Fred W Rankin to Expression of Appreciation of House

Dr Fred W Rankin Retiring President addressed the House as follows

Mr Speaker and Members of the House It is a great satisfaction to me to express to you my appreciation for this generous motion which you have just passed and to tell you that the two years which I have served you in the capacity of President-Elect and President of this Association have been very happy although arduous years and I can assure you that I have taken the responsibility seriously and that as time goes on I hope that I may be able to continue to do whatever is in my power to forward the progress of the American Medical Association. Thank you

On motion of Dr E E Barlow Arkansas, seconded and carried unanimously, the House adjourned sine die at 12 05 p m

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—H R 2935 has passed the House, making appropriations for the Department of Labor, the Federal Security Agency and related independent agencies for the fiscal year ending June 30, 1944. Among other sums appropriated this bill makes available to the Children's Bureau \$4,000,000 for grants to states to provide, in addition to similar services otherwise available, medical, nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the United States under plans developed and administered by state health agencies and approved by the chief of the Children's Bureau. No part of any appropriation for the Children's Bureau, the bill provides, may be used to promulgate or carry out any instruction, order or regulation relating to the care of obstetric cases which discriminates between persons licensed under state law to practice obstetrics. The bill also makes available to the Public Health Service the sum of \$3,500,000 for the training of nurses. H R 2536 has been reported to the Senate, a bill to provide for the promotion of vocational rehabilitation of persons disabled in industry or otherwise.

Bill Introduced—H R 2947, introduced by Representative Coffee Washington, proposes to authorize an appropriation of \$18,000,000 for the fiscal year ending June 30, 1945 [sic] and for each fiscal year thereafter such sums as may be necessary to enable each state to provide medical care to recipients of public assistance under the titles of the Social Security Act relating to old age assistance, aid to dependent children and aid to the blind. The term "medical care" is defined to include only such services, supplies and appliances for the diagnosis, cure, mitigation, treatment or prevention of disease, or for the purpose of affecting any structure or function of the body, as may be approved in regulations of the Social Security Board.

STATE MEDICAL LEGISLATION

Alabama

Bill Introduced—S 302 proposes the creation of a mental hygiene clinic to advise and consult with individual citizens of the state who recognize or feel that they have mental problems about which they may be concerned threatening to affect their own mental health, to consult and advise with the relatives or guardian of persons about whom they may be interested anxious or concerned on the account of some suspected or approaching or threatening mental health, to admit such person for examination, observation, study, consultation, diagnosis, opinion and to advise as to what course shall be followed in the care, planning for and treatment of such individuals.

California

Bills Enacted—A 257 has become chapter 1098 of the Laws of 1943. It amends the health and safety code by requiring the state department of public health to seek out children with impaired sense of hearing, especially in the primary and grammar grades of all schools. It shall employ for such diagnostic investigation only trained otologists. This law does not give the department power to require medical or physical examination of children without consent of the parent or guardian, however. A 686 has become chapter 1061 of the Laws of 1943. It amends the Health and Safety Code by providing, among other things, that the state director of health shall be a doctor of medicine eligible to license to practice in California, with at least one year's postgraduate training in public health and a minimum of five years' practical experience as an administrative officer in a well organized health department.

Connecticut

Bill Enacted—H 902 has become chapter 308 of the Laws of 1943. It provides that licensed physicians serving in the armed forces of the United States shall not be required to renew their certificates until the next renewal period immediately following discharge from such service or the renewal period following the second year after the cessation of hostilities, whichever is first.

Florida

Bills Enacted—S 264 was approved, May 31. It provides that any member of the armed forces of the United States on active duty who, at the time of entering on active duty, was in good standing with any administrative board (which includes the state board of medical examiners) of the state of Florida and was entitled to practice or engage in his profession shall be kept in good standing by such administrative board without registering, paying dues or fees or performing any other act on his part to be performed, as long as he is a member of the armed forces on active duty and for a period of six months after his discharge therefrom. S 301 was approved, June 11. It provides an appropriation of \$20,000 to provide for the vocational rehabilitation of disabled persons who are physically incapable of earning a livelihood but whose disabilities appear to be amenable to treatment or surgery and could be removed or materially diminished to the extent that such persons would then be physically able to engage in remunerative employment. S 367 was approved, June 11. It provides for the creation of a Florida board of massage to examine persons desiring to practice massage, defined as the art of body massage, either by the hand or by mechanical apparatus, oil rubs, gymnastics, colon irrigations, hot and cold packs, cabinet baths (excluding fever therapy), tub, shower, sitz and similar baths. S 616 was approved, June 6. It authorizes state, county and municipal health officers to commit persons within their respective jurisdictions who are infected with venereal disease to quarantine and compulsory treatment in any hospital within the state whenever in their judgment it is necessary to protect the public health. S 641 was approved, June 11. It amends the medical practice act by providing that the clerk of the circuit court shall not accept for recording and shall not record any license to practice medicine dated after the effective date of the act unless the same has been presented to him for recording on or before sixty days after the date of the license and provided further that no license to practice medicine dated prior to the effective date of the act may be recorded by the clerk of the circuit court unless it has been presented to him for recording on or before the expiration of six months from and after the effective date of the act or within sixty days after the date of recertification thereof by the board of medical examiners.

Illinois

Bill Introduced—H 704, to amend the law relating to nursing homes, proposes that such home will not be denied a license because it is conducted in accordance with the tenets of any well recognized church or denomination and the treatment therein is confined to prayer and spiritual means as an exercise or enjoyment of religious freedom. The inspection of such institutions would be confined to the adequacy of the facilities to furnish such service and the sanitary and fire protection facilities thereof.

South Carolina

Bill Enacted—H 141 has become act 354 of the Laws of 1943. It provides that receipted hospital bills shall be an exemption under the state income tax law.

Wisconsin

Bills Enacted—A J R 53 has become chapter Res No 38 of the Laws of 1943. It is a resolution that the state board of health, state board of medical examiners, state board of dental examiners and the several professional societies be requested to ask all practicing physicians and dentists to ascertain, as far as possible, whether patients are now or are on any subsequent date veterans of the present war and, if so, to preserve case histories thereof for at least six years after the date of the last professional service rendered. A bill has become chapter 304 of the Laws of 1943. It amends the law relating to the licensing of nurses by providing for the addition thereto of regulations for the licensing of "licensed attendants" who are authorized to perform simple procedures in the physical care of a patient and such other procedures as may be directed by the attending physician.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY FINDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITY THE NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Governor Approves Four Year Medical School—The Medical College of Alabama will be established under a bill recently signed by the governor which appropriates a million dollars for land buildings and equipment and \$366,750 for each of the fiscal years ending Sept 30 1944 and Sept 30 1945. The governor is to appoint a building commission to select a site for the school which will operate as a part of the University of Alabama University. The bill also authorized the creation of a Physicians Advisory Board consisting of five physicians who shall be members in good standing of the state medical association and shall reside in different sections of the state. This board will cooperate with the commission in its activities toward the construction of the school. The bill provides that the board of trustees of the University of Alabama is authorized to establish a scholarship for each county in the state in the amount of \$400 a year for the benefit of one resident of each county payable from the annual state appropriation to the school of medicine.

CALIFORNIA

State Board Changes Time for Examinations—The state board of medical examiners at its recent meeting in Los Angeles decided that it would give written examinations to candidates for licensure whenever a sufficient number of such applications are on file. The action was to aid in every possible way in the war effort. In the past the board has held four written examinations a year.

Orders License Restored—Newspapers recently reported that the license of Dr Thomas D Wyatt Redding to practice medicine has been restored by a writ of mandate issued by Superior Judge Edward Murphy in San Francisco. The physician who has twice had his license revoked for performing allegedly illegal operations brought action against the state board of medical examiners, claiming that it had exceeded its jurisdiction in revoking his license the second time.

Opening for Physician—The Los Angeles County Civil Service Commission is seeking a doctor of medicine to conduct venereal disease clinics and perform other venereal disease work in the Los Angeles County Health Department. Men under 55 years of age who have graduated from an accredited medical school and who have completed at least one year's internship in an approved hospital are eligible for the position which offers a salary of \$296 a month. The examination will be held in Los Angeles and may also be held in other parts of the country if warranted by the applications filed. Information may be obtained from the office of the commission Room 102 Hall of Records Los Angeles 12 California. Applications must be filed on or before Wednesday July 7.

IDAHO

Annual Registration Due July 1—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the Department of Law Enforcement and at that time to pay a fee of \$2. If a licensee has not paid the annual registration fee by October 1 his license can be canceled but will be restored within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been canceled for more than five years it can be reinstated only on the payment of \$25 and on the licensee's passing an examination the nature of which shall be determined by the Department of Law Enforcement.

ILLINOIS

Society News—Dr Walter E Foley Davenport Iowa was elected president of the Iowa-Illinois Central District Medical Association at its meeting in Rock Island May 27. He succeeds Dr David B Freeman Moline. Other officers include Lieut Col Herbert P Miller M R C of Rock Island now stationed at Fort Sheridan vice president Dr James Dunn Davenport secretary and Dr Florens E Bollaert East Moline treasurer.

Chicago

Chicago Alumni Awarded Citations—On June 12 the University of Chicago awarded citations as distinguished alumni to fifty-five members of the college classes prior to 1911. Among those honored are Drs Morris Fishbein Arno B Luckhardt Franklin C McLern and Rollin T Woodvatt.

Hektoen Institute for Medical Research—On July 2 the eightieth birthday of Dr Ludwig Hektoen the Hektoen Institute for Medical Research of Cook County will be dedicated in his honor. Dr Morris Fishbein Editor of THE JOURNAL will preside at the ceremonies which will be held at 10 a m. The building formerly the McCormick Institute for Infectious Diseases has been purchased by the board of Cook County commissioners. A portion of the building is already in use. A plaque bearing a bas-relief of Dr Hektoen will be unveiled in the entrance of the institute. The presentation will be made by Clayton F Smith president of the board of commissioners and Dr Karl Meyer will receive it on behalf of the institute. The board of trustees for the Hektoen Institute for Medical Research of Cook County established by the Cook County Board comprises:

Mr Smith
Dr Raymond W McVerly president of staff Cook County Hospital
Col Albert A Sprague
Dr Meyer medical superintendent Cook County Hospital and other Cook County institution
Frank Bobrytzka chairman Hospital Committee Cook County Board of Commissioners
William McFetridge international president Building Service Employees Union
Brig Gen Frank Schwengel president Seagram Distilleries Inc
Dr Fishbein
Dr Andrew C Ivy scientific director Naval Medical Research Institute Bethesda Md
Dr Raymond B Allen executive dean of Colleges of Pharmacy Dentistry and Medicine and dean of College of Medicine University of Illinois
Dr Italo F Volini chairman of the Department of Medicine Loyola University School of Medicine
Dr Marshall Davison chairman Department of Surgery Cook County Hospital
Dr Maurice L Blatt head of Children's Division Cook County Hospital
Lieut Col Samuel J Hoffman M C chief of medical personnel Sixth Service Command
Dr James P Simonds professor of pathology Northwestern University Medical School
Dr Aaron Arkin chairman Department of Medicine Cook County Graduate School of Medicine
Dr Hans Popper director of laboratories Cook County Hospital
Dr Frederick Steigmann director of therapeutics Cook County Hospital

LOUISIANA

University News—At a meeting of the History of Medicine Society of Tulane University, April 15 the Rudolph Matas Award for the best paper on the history of medicine presented before the society was given to Mr Charles M Wilson senior in the medical school, for his paper on American Contributions to Neurosurgery. The I I Lemann Award for the best discussion before the society was presented to Mr Leonard K Knapp junior in the medical school, for his discussion on aviation medicine. The presentations were made by Dr B Bernard Weinstein New Orleans instructor in gynecology in the medical school Harold Cummins, Ph D, New Orleans, professor of microscopic anatomy was the principal speaker discussing Extra Medical Interests of Charles Richet Arthur Conan Doyle and Dr Krandon.

New Orleans Venereal Disease Campaign—A citywide venereal disease campaign committee was recently formed in New Orleans after a drive against prostitution when 820 women were arrested and examined between July 14 1942 and Feb 1 1943. The group had a reported infection rate of 80 per cent. The work of the new committee is financed through contributions by the city individuals civic agencies and commercial firms. The facilities of practically every medium of communication were made available. According to the *Har Letter* although the main drive of the campaign was scheduled originally for only two weeks the campaign committee decided to expand and continue for a longer period. The members of the committee were asked to continue to serve for several more months and activities directed at education of the man in the street were intensified.

Grants to Medical School—According to the *Tulanean* a fund of \$30,000 for the establishment of a biologic chemistry division of the Tulane University of Louisiana School of Medicine was bequeathed to the university by Miss Aimee Creagh Denis. The fund is designed to establish the Willey-Lover Denis Fellowship in memory of Miss Denis's sister Willey L Denis a biochemist. Three grants for work in tropical medicine and cancer research have been made to the university. A grant of \$10,000 for the making of a colored educational

motion picture on amebic dysentery has been given by the Wyeth pharmaceutical house of Philadelphia. The picture will be used in teaching and training physicians, students and nurses. A gift of \$8,500 has been given the department by the G. E. Seale pharmaceutical house of Chicago, and an unspecified amount has been given to the department of surgery for the study of cancer by Theodore Brent, New Orleans, president of the Mississippi Delta Shipping Company.

MINNESOTA

Annual Journal-Lancet Lecture—On May 19 Dr. Ernst Gellhorn, professor of physiology, University of Illinois College of Medicine, Chicago, delivered the third annual Journal-Lancet lecture at the University of Minnesota Medical School, Minneapolis. Dr. Gellhorn's subject was "Experimental Studies: Conditioned Reflexes and Their Implications for Medical Problems."

Narcotic Prescriptions Forged—Helen Geneva Rudd, Minneapolis, was recently ordered by Federal Judge Gurnett H. Nordbye to the U. S. Public Health Service Hospital at Lexington, Ky., for treatment of drug addiction. Mrs. Rudd had pleaded guilty to four counts of an indictment charging her with forging medical prescriptions for narcotic drugs. She was placed on probation for three years on condition that she be taken to the hospital at Lexington and that she be not released until the medical authorities of the hospital pronounced her cured. An investigation by the Federal Bureau of Narcotics disclosed that Mrs. Rudd's addiction dates back about twenty years; she pleaded guilty in 1934, after two years she violated her probation and was taken to the Women's Reformatory at Alderson, W. Va., where she served fourteen months.

MONTANA

State Medical Meeting—The sixty-fifth annual session of the Medical Association of Montana will be held in Billings, July 7-8, under the presidency of Dr. Ernest D. Hitchcock, Great Falls. Among the speakers will be:

Dr. William M. Bane, Denver, Treatment of Eye Diseases by the General Practitioner
Dr. Laurence J. Howard, Great Falls, Hematuria and Its Significance
Dr. Glenn A. Carmichael, Butte, Management of Breast Presentation
Dr. Irving J. Bridgman, Terry, A Discussion of Some of the Newer Drugs
Dr. Wayne Gordon, Billings, Gastritis: Diagnosis and Clinical Significance
Major Alexander P. Ormond, M. C., A. U. S., Great Falls, The Wartime Spread of Communicable Diseases
Dr. Harry O. Drew, Billings, The Sex Hormones and Their Relationship
Dr. Halvard M. Blegen, Jr., Missouri, Gastrocolic Fistula

Dr. E. Thompson Bell, professor of pathology, University of Minnesota Medical School, Minneapolis, will conduct a panel discussion Thursday on "Diseases of the Kidney and Hypertension." He will also address the annual banquet on "Diseases of the Kidney."

NEW JERSEY

Medical School Plan Rejected—The state board of education on June 11 denied an application of a corporation known as the Essex College of Medicine and Surgery, Newark, for permission to confer the degree of doctor of medicine, according to the *New York Times*. The action was said to be taken on the ground that the school "is only a paper institution." The *Times* further reported that the state board of education unanimously approved a report of a committee stating that the Essex College of Medicine and Surgery was at present inadequately financed, lacked library facilities and had no faculty.

NEW YORK

Report of Emergency Food Commission—A four point nutrition program was recommended in the first report of the Emergency Food Commission of the State of New York, June 7. The program covering food preservation, protection of milk and egg supply, research for new foods and nutritional guidance, is discussed in the report of the commission with a view to showing what improvements have already been accomplished and what must be made in the future to maintain the public health and morale in the face of a necessary shift to a wartime diet lacking the usual amount of animal products.

Expansion of Health Teaching—The New York State Board of Regents has authorized the expansion of teaching on health and safety in the senior high schools, the new program to be given one unit of credit. The new regulations covering health teaching make it the duty of the trustees and boards of education to provide a satisfactory program in health and safety in accordance with the needs of all pupils from the kindergarten and primary through the senior high school

grades. In the junior and senior high school grades, health must be taught by teachers with approved preparation. *Health News* announces that a member of each faculty with such preparation must be designated as health coordinator in order that the entire faculty may cooperate in realizing the potential health teaching values of the school program.

New York City

Chinese Blood Bank—On June 5 the first Chinese blood bank in the city was opened under the auspices of the American Bureau for Medical Aid to China. The bank will take blood from Chinese-Americans and send plasma by air to Chinese soldiers. The medical staff members of the bank are all Chinese, have had special training in this work and will eventually go to China as a unit to set up the first blood bank there.

Institute for Forensic Medicine—The planning of an Institute of Forensic Medicine in New York was announced by Mayor La Guardia at the opening session of the annual assembly of the International College of Surgeons, June 14. The proposed institute will serve as a center for all matters pertaining to medical jurisprudence. Arrangements are being made to acquire the land for the building, which will be situated near Bellevue Hospital. The new center will be operated in conjunction with one or two medical schools of the city, the chief medical examiner's office and all of the city's hospitals. It will have its own morgue, laboratory, dissection room, class rooms and chemical division.

OHIO

Outbreak of Smallpox—Wholesale vaccination was carried out recently in a number of counties in Ohio because of the 97 cases of smallpox which were reported to the state department of health between January 1 to May 15. The state medical journal reported that a recent outbreak of the disease in Steubenville and Jefferson County created a serious problem not only in Ohio but also in West Virginia, because a large number of residents of Ohio are employed in the steel mills in West Virginia. In Steubenville, a city of about 35,000 population, 28,186 persons were vaccinated in a period of three weeks and many thousands of residents in other parts of Jefferson County were vaccinated during the same period of time. The intensive program of vaccination became necessary when several families, believing that they had chickenpox, exposed a large number of residents to smallpox. Concentrated programs of vaccination were conducted in other counties where the disease occurred and Cleveland is now considering one in the schools and industry.

Training in Health Education at Cleveland Museum—The Cleveland Health Museum announces a course of instruction from August 9 to September 4 for twenty-seven students in health education from the University of North Carolina, Chapel Hill, who will work as museum interns. The students will do laboratory work and gain field experience in the methods of health education, especially in health exhibits. Among the students are seventeen persons who were awarded fellowships by the U. S. Public Health Service from a grant made available by the W. K. Kellogg Foundation. The four week course at the museum is part of a three months supervised field experience required in addition to nine months' academic training in order to obtain a master of science in public health. One student comes from Lima, Peru. The course will be conducted by Dr. Bruno Gebhard, Cleveland, who is director of the Cleveland Health Museum and an associate in health education, Western Reserve University School of Medicine. Besides instruction in the principles and methods of visual health education, the students will gain practical experiences in three work units. The first one deals with ideas, facts, figures and manuscripts. Another unit is centered around designing, constructing and budgeting of exhibits. And the third work unit will handle placement, publicity, visitors' reaction and follow-up. The museum's facilities including the work shops, the loan service, traveling exhibits and the film library, and of course the museum's own exhibits will be used for this training.

PENNSYLVANIA

Changes in Health Officers—Dr. Thomas M. Thompson, Philipsburg, district medical officer for district 9, consisting of Clearfield, Clinton and Centre counties, has been transferred to district 4, composed of Bucks and Montgomery counties, with headquarters in Norristown. Dr. George R. Good, Altoona, district medical officer for district 10, will have temporary charge of district 9. District 10 includes Huntingdon, Blair and Cambria counties. Dr. Thompson succeeds the late Dr. Howard W. Hassell, Bridgeport.

Philadelphia

Dr Fay Acting Dean at Woman's Medical College—Marion S Fay, PhD, since 1935 professor of physiologic chemistry at the Woman's Medical College of Pennsylvania, has been appointed acting dean for the duration of the war to fill the vacancy caused by the commissioning of Dr Margaret D Crughill as major in the medical corps of the army. Dr Fay began her services as acting dean on May 28 when Major Crughill reported to the Surgeon General's Office in Washington, D C. Dr Fay was born in New Orleans. She graduated at Newcomb College, New Orleans, in 1915. She received her masters degree at the University of Colorado Boulder in 1922 and her PhD at Yale University, New Haven, in 1925. She was associate professor at the University of Texas Medical Branch, Galveston, when she joined the Philadelphia faculty.

Symposium on Poliomyelitis—The Philadelphia chapter of the National Foundation for Infantile Paralysis is sponsoring a series of eight lectures on poliomyelitis for physicians, nurses and physical therapists. The lectures which opened on June 14 are given on Mondays and Thursdays in the Philadelphia County Medical Society. Among the speakers are:

- Dr Don W Cudakunst, New York, medical director, National Foundation for Infantile Paralysis, Introduction and Chemotherapy.
- James H Jones, PhD, assistant professor of physiologic chemistry, University of Pennsylvania School of Medicine, Nutrition.
- Dr Pascal L Lucchesi, acting assistant director of public health of Philadelphia, Diagnostic Signs.
- Dr Kenneth F Maxey, professor of epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Epidemiology.
- Dr Howard A Howe, associate professor of epidemiology, Johns Hopkins University School of Hygiene and Public Health, Neuro-pathology.
- Herman Kabat, PhD, pharmacologist at the National Institute of Health, Bethesda, Md, Neurophysiology.
- Dr DeForest P Willard, professor of orthopedics, the Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania, Orthopedic Surgery.

TEXAS

Baylor Graduates Last Class in Dallas—Arrangements are being made for the transfer of Baylor University College of Medicine from Dallas to Houston under the direction of Dr Walter H Moursund Sr, dean. At the recent graduation of the last class of Baylor in the Dallas school, Dr Ernst W Bertner, acting director of the M D Anderson Hospital for Cancer Research, Houston, delivered the address on "A New Era in Medicine."

Conference on Hay Fever and Allergy—A special conference on hay fever and allergy met at the University of Texas Medical Branch, Galveston, June 13 under the leadership of Dr William L Marr, director of the allergy clinic of the medical school and Dr Ralph Bowen, Houston. The conference has been organized to coordinate the work of Texas physicians who are interested in the problems of hay fever and allergy in the Southwest.

WASHINGTON

Annual Registration Due July 1—All practitioners of medicine and surgery holding licenses to practice in Washington are required by law to register annually on or before July 1 with the Director of Licenses and at that time to pay a fee of \$5, thereby renewing their licenses for one year. Failure on the part of a licensee timely to register and pay the required fee renders his license to practice invalid but his license may be reinstated on written application to the director and on payment of the delinquent fees and a penalty of \$10.

WISCONSIN

State Medical Meeting—The one hundred and second annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee, September 13-15 under the presidency of Dr Russell M Kurten, Racine. According to a preliminary program a feature of the meeting will be a symposium on the liver and one on peptic ulcer. Round table breakfasts will be devoted to the following subjects: bedside medicine and newer drugs; prevention and treatment of wound infections; improvisations to cope with medical emergencies in the home; precautions in telephone prescribing; medication for common skin diseases and the use and abuse of sulphonamide drugs. A separate program has been arranged for hospital superintendents, chiefs of staff, secretaries of staff, hospital administrators and nurses, the program to cover a discussion of recent legal decisions of importance to physicians in hospitals, problems concerning graduate education and employment of nurses, interns and residents, authorization required for professional

procedures, Wisconsin Hospital and medical payments plan, professional accounting, relationship between the lay hospital board and the hospital staff, a small hospital library and inter-hospital relations.

GENERAL

Institute for Hospital Administrators—The eleventh Chicago Institute for Hospital Administrators will be held at the Knickerbocker Hotel, August 30-September 10, under the auspices of the American Hospital Association and in cooperation with the American College of Hospital Administrators, American College of Surgeons, American Medical Association and the Chicago Hospital Council. The institute will be under the direction of Dr Malcolm T MacEachern, Chicago, and lectures, demonstrations and round tables will be based on practical means to help solve present-day hospital problems. A minimum of fifty registrants must be assured by July 15 to hold the institute. Additional information may be obtained from Miss Agnes M McCann, secretary of the institute for hospital administrators, American Hospital Association, 18 East Division Street, Chicago.

Infantile Paralysis Foundation Expands Board of Trustees—The recent addition of nine members to the board of trustees of the National Foundation for Infantile Paralysis brings the total number of trustees to thirty-nine. The late Mr Edsel Ford has been succeeded on the board by one of his sons, Lieut Henry Ford II. Other new members are Benjamin F Fairless, president, U S Steel Corporation; Pittsburgh, Edward S French, president, Boston and Maine Railroad, Boston; Walter S Gifford, president, American Telephone and Telegraph Company, New York; Clarence G Michalis, chairman and trustee, Seamens Bank for Savings, New York; Bayard F Pope, chairman, Marine Midland Corporation, New York; David Sarnoff, president, Radio Corporation of America, New York; Juan T Trippe, president, Pan American Airways, New York; and Joseph E Uihlein Sr, vice president, Joseph Schlitz Brewing Company, Milwaukee.

CORRECTIONS

Connor Odor Adsorber—In a letter from Dr Levin published in the Queries and Minor Notes on May 13, reference was made to the Connor Odor Adsorber. This is manufactured by the W B Connor Engineering Corporation instead of the General Electric Company, as stated in the letter.

Place of Annual Session—On page 507 of THE JOURNAL for June 19 a statement appears to the effect that the annual session of the American Medical Association in 1944 is scheduled to be held in New York and the annual session for 1945 in St Louis. That statement is in error in that the annual session scheduled for 1944 is to be held in St. Louis and the annual session for 1945 is to be held in New York. At the meeting of the House of Delegates in Chicago on June 9 San Francisco was selected as the place of meeting for 1946. As stated in THE JOURNAL these designations are subject to final action of the Board of Trustees and depend on special conditions that may be created by the war.

Government Services

Dr Spencer Appointed Director of Cancer Institute

Roscoe Roy Spencer, medical director, U S Public Health Service and assistant chief of the National Cancer Institute, Bethesda, Md, has been appointed chief of the institute effective August 31. He will succeed Carl Voegtlin, PhD, who is retiring as director. Dr Spencer was born in Virginia July 28, 1888. He graduated at Johns Hopkins University School of Medicine, Baltimore, in 1913 and in the same year joined the U S Public Health Service. He was sanitary adviser to the Navy Department 1917-1918, officer in charge of bubonic plague suppressive measures at Pensacola, Fla. 1919-1921 and in charge of investigations of Rocky Mountain spotted fever 1922-1929. In 1930 a year after he with Ralph R Parker, PhD, Hamilton, Mont., wrote a volume on spotted fever. Dr Spencer received a gold medal from the American Medical Association for his discovery of a preventive vaccine for the disease. Dr Voegtlin will retire from the public health service. From 1913 to 1939 he was chief of the division of pharmacology of the National Institute of Health. In 1938 he was appointed the first director of the National Cancer Institute.

New Measures in the Campaign Against Tuberculosis

The minister of health, Mr. Ernest Brown, has announced the fact that, in spite of the war, the number of deaths from all forms of tuberculosis in 1942 was 25,500 less than that in the two previous years 1940 and 1941, when it was 28,000. The figure of last year was the same as that for the prewar year of 1938, which was the lowest on record, and it was well under half of that for 1918. Who would have dared, asked the minister, to hope that the tuberculosis position in the third year of the war would be so good? But he said that there was a small rise of about 3 per cent in the number of new cases last year, and under the trying conditions of total war there can be no assurance that the death rate from tuberculosis will not rise again. The Ministry of Health has therefore decided to intensify the offensive against pulmonary tuberculosis. It is doing two things: introducing the newest method of chest examination by miniature radiography and starting a scheme of special allowances which will enable those who require treatment for pulmonary tuberculosis, in the interest of public health as well as their own, to undertake it without anxiety about those whom they support.

MASS MINATURE RADIOGRAPHY

The weak point in the attack on tuberculosis has been inability to get the individual case soon enough. Early detection is vital. For this mass miniature radiography was recommended by a special committee of the Medical Research Council under the chairmanship of Lord Dawson, appointed at the minister's request to investigate the wartime increase in tuberculosis. A detailed scheme covering the application of miniature mass radiography in all its aspects has been drawn up and brought before all the local health authorities. There must be some delay in obtaining delivery of the highly technical machines necessary and it may take at least a year before a network of mass miniature radiography units covers the populous areas of the country. It is hoped that eventually this radiography will become part of routine health examinations. The aim is to detect pulmonary tuberculosis before symptoms have appeared and thus give the best prospect of cure. So far only about three out of every thousand examined have been found tuberculous. The machines can photograph chests at the rate of more than a hundred an hour, using ordinary cinema film. Each negative, only about 1 inch square, is projected on a screen and examined by experts. In forty to fifty of each thousand there is some sign which indicates the advisability of further investigation. A full size x-ray film and other tests may then show that the suspicion is unfounded, or perhaps the need for another test after an interval.

THE NEW ALLOWANCES

The object of the ministry is that any one in whom miniature radiography discloses active tuberculosis should undergo treatment without delay, even though the disease has not reached a disabling stage or, indeed, has caused him to feel unwell or unfit for work. For this reason the government has decided to provide special maintenance allowances. These will enable the person to give up work for a time and undergo treatment while there is every prospect of recovery. Another reason for introducing these new allowances is that tuberculosis stands alone as a social disease of prolonged infectivity. In the interests of the community, especially in wartime, it calls for special measures to check its spread and consequent drain on

man and woman power. The new allowances will comprise what will be called "maintenance allowances" based on a standard scale and without any test as to means. To these may be added, at the discretion of the local health authority where they are satisfied as to need, extra grants toward meeting standing commitments which the patient could not otherwise meet, such as high purchase instalments, high rent or rates, insurance premiums and school fees.

Damages for Negligence Awarded Against a Physician for Awaiting the Pathologist's Report Before Treating Diphtheria

An unusual case in which damages for negligence were awarded against a physician has occurred in the high court. On Sept. 5, 1940 the physician was called to a boy who complained of his throat. The physician did not at first suspect diphtheria and therefore he did not take a swab until the 13th. It was four days before he received the pathologist's report and the boy was not removed to a hospital until the 17th, when he was hopelessly ill with diphtheria. Antitoxin was given at once but death took place two days later. The judge found the physician negligent at least from September 9, when he ought to have seen symptoms which the boy's mother had seen on the previous day. The judge commented on the fact that the physician was in charge of a case of diphtheria for eleven days and gave no treatment for the disease. He also criticized his omission to do anything while awaiting the pathologist's report for four days. It was impossible to say that with earlier treatment the boy would have recovered or that the death was attributable to the treatment. But there was a good chance of recovery if the patient had been properly treated.

An unusual feature of the case was that no evidence was called for the defense. The physician contended, doubtless under legal advice, that he should not be found guilty of negligence in the absence of medical evidence. The judge dissented from this submission and said "The trusting public would be hopelessly at the mercy of the medical profession" if this argument held. He also commented on the silence of the physician saying "It is the first time in my experience that a medical man charged with negligence has refrained from going into the witness box to explain, excuse or throw light on what has happened." He awarded \$300 damages with costs. However, notice of appeal against this judgment was given, pending which a stay of execution was granted.

Commenting on the case, the *Lancet* says that it would be a pity if it became a convention that a defendant because he is a physician must go into the witness box and call evidence, though defendants of other callings would in a like situation be allowed to claim their right to plead that no sufficient case had been made for them to rebut. It would be lamentable if the physician's vocation exposed him to the forensic duty of clearing himself whenever his professional judgment is challenged. Negligence of a physician is normally established by giving proof of what a reasonably careful one would do in the circumstances. It will be a surprise to the profession if such proof can be given by lay witnesses or if the court itself can so far abandon the rule of judicial ignorance as to declare on its own unaided knowledge the standard of due professional care. The fact that a physician did not treat a patient who died of diphtheria for the disease before the pathologist's report was available need not be automatic proof of negligence.

Simplification in Prescribing Spectacle Lenses Desirable

The war effort has hindered the production of spectacle lenses as of many other things. Because of the difficulty the Council of British Ophthalmologists suggest a simplification of the prescription of lenses. It recommends (1) discontinuance of prescribing lenses in steps less than 0.25 diopter, (2) reduc-

the prescribing of prisms to a minimum and (3) in the higher ranges say above 4 diopters, reducing the prescription of lens powers in steps less than 0.5 diopter to a minimum. These recommendations were adopted in the army some time ago and their adoption in civilian practice would materially aid the situation.

An Experiment in the Prevention of Endemic Goiter

In 1939 Dr. A. Lobo Leite described a goitrogenous region in the central part of the state of Minas Gerais, comprising the counties of Ouro Preto, Congonhas and Latacê, a region completely free from Chagas disease (American trypanosomiasis) despite the vicinity of several areas stricken by this disease. In this region the endemic disease presents a complex of symptoms similar to that described in other countries: goiter, cretinism, dwarfism, mental debility. Of all the elements of this complex, goiter is the most frequent although the most benign and many cases of goiter are not accompanied by any other element of the complex. Cases of psychoses are relatively common which is perhaps related to the complex. The medium and small diffuse enlargements of the thyroid are the most frequent nodular goiter appearing as a rule only in adult age. The recent diffuse goiter is very responsive to treatment with iodine. A representative sample of 2,574 school children has been routinely examined for the detection of goiter and the thyroids classified according to the Marine scale. Of the total 1,437 (55.8 per cent) had type 1 thyroid (normal), 920 (35.7 per cent) had type 2 thyroids (small goiter) and 217 (8.4 per cent) had type 3 thyroid (medium goiter). Types 2 and 3 taken together represented 44.2 per cent of the sample. The whole of this goitrogenous region lies about 3,500 feet above sea level and the soil belongs to the primitive era, the luromian system. The region is clearly deficient in iodine as it is easy to see from the average amount of this element in the water supply and in the principal vegetables used as food: water 0.18 microgram per liter, beans 6.0 micrograms per kilogram, potatoes 5.1 micrograms per kilogram, rice 2.0 micrograms per kilogram, corn 1.4 micrograms per kilogram and manihot less than 1.0 microgram per kilogram.

With the cooperation of the school authorities, a prophylactic station has been established with the main purpose of distributing to the school children confections with 10 mg. of potassium iodide each, twice a week. Dr. Lobo Leite considers this dose rather high but intended with it to render possible the formation of an iodine reserve as well as for treatment at the same time. This high dosage is intended also to compensate for the school vacation time (from January to March). Between April and December 1941, 855 Kg. of confections was distributed corresponding to 1,983 Gm. of potassium iodide to about 5 thousand school children. The work continued during the year 1942 and at the end of the year Dr. Lobo Leite took a new survey of the situation, the results of which will soon be published.

BCG Immunization in Brazil

The BCG method of tuberculosis immunization has been in course of development in Brazil since August 1927 when the Ataulpho de Paiva Foundation began to prepare the immunizing material and to vaccinate a part of the infants of the Federal District (city of Rio de Janeiro). With 17,573 vaccinations performed in 1942 in the city of Rio de Janeiro (about 50 per cent of the total number of live births), the number of children immunized in the city has reached the total of 123,493. Of this total 32,589 children or 26.39 per cent have been medically controlled in clinics. So large a percentage of controlled children in BCG immunization has not been attained in

any other place. Of the total of 17,573 children vaccinated in 1942, the immunization was performed by spontaneous request from the families of 5,520 or 31.45 per cent, which shows the acceptance of this prophylactic measure by the population. In November of last year an agreement was reached between the Ataulpho de Paiva Foundation and the federal government to extend the supply of the immunizing material to several of the states of Brazil through the action of the Tuberculosis Division of the National Department of Health. During the year 1942, 62,180 doses of the vaccinating material were sent to several states of Brazil.

Brief Items

A few months ago the Brazilian government created a Book of Merit in which to inscribe the names of the greatest living men of the country. The honor is considered exceptional and the few names up to now included in the book have been selected with utmost care. One of these names is that of Dr. Vital Brazil, the founder of the Butantan Institute of São Paulo, one of the pioneer laboratories in the study of ophiology and the preparation of antiophidic serums. Dr. Vital Brazil is now director of the Vital Brazil Institute of Niterói, state of Rio de Janeiro, a great laboratory where many biologic products for medical therapy are prepared.

Dr. Raul L. da Cunha, president of the University of Rio de Janeiro and Drs. Alfredo Monteiro and H. Annes Dias, professor of surgery and of medicine at the medical school of the same university, came back recently from a trip to Santiago, Chile, where they attended the commemoration of the centenary of the foundation of the University of Santiago. These three Brazilian medical men received the degree of professors honoris causa from that university.

Dr. Emilio Corbiere from Buenos Aires recently spent a few days in Rio de Janeiro as a representative of several medical institutions of Argentina. Dr. Corbiere, who came in a mission of scientific interchange, delivered medical lectures at the National Academy of Medicine and before the Medical Association of Rio de Janeiro.

A special course in war traumatology has been established at the medical school of the University of Rio de Janeiro. This course is under the direction of Dr. Barbosa Vianna, professor of traumatology and orthopedic surgery at the same school.

A School of Aviation Medicine has been founded by the Ministry of Aeronautics. The new school, located at Atonso's Field near Rio de Janeiro, is under the direction of Col. Dr. Godmilho Santos.

Marriages

WILLIAM JAMES MCKINNON, Manton, N. C. to Miss Corinne Louise Stimax of Westminster, Md. in New York, May 29.

LUTHER BRADFORD WATERS, JR., Lynchburg, Va. to Miss Margaret Mae Hughes of Colerain, N. C. in Norfolk, May 17.

CHARLES DICK ROLLINS, Henderson, N. C. to Miss Martha E. Laney of Camden, Ark. at Walla Walla, Wash., May 14.

WILLIAM HARVEY PATRICK, Chocowinity, N. C. to Miss Nellie Evangeline Guy in Clements, Md., May 16.

FRANK L. ENGEL, New Haven, Conn. to Miss Mildred Goldtaden of Norwich, New York, May 25.

HAROLD GREELEY NOYES, New York, to Mrs. Bessie Clements Murrelle in Greenwich, Conn., May 22.

CHARLES FREDERICK DOWNING, Nashville, Tenn. to Miss Juliette McNeil in Knoxville, May 8.

JOHN FRANCIS McGRATH, New York, to Mrs. Inez Thorpe Ford of Georgetown, S. C., May 25.

SANDOR ALEXANDER NADAS, to Miss Mary Elizabeth McClearen, both of Boston, recently.

FRANCIS C. ANDERSON, Cadillac, Mich. to Miss Dorothy Mae Larson at Ann Arbor, recently.

Deaths

Isador Henry Coriat ⊕ Boston, Tufts College Medical School, Boston, 1900, instructor of neurology at his alma mater from 1914 to 1916, instructor, supervising analyst and training analyst, Boston Psychoanalytic Institute, neurologist to the medical advisory board and contract surgeon in neuropsychiatry for the U S Army during World War I, specialist certified by the American Board of Psychiatry and Neurology, Inc., member, twice president, 1924-1925 and 1936-1937, and vice president, 1935-1936, of the American Psychoanalytic Association, member and vice president, 1931-1932, of the American Psychopathological Association, member of the International Psychoanalytic Association and vice president, 1936-1937, president of the Boston Psychoanalytic Society from 1930 to 1932 and 1941-1942, member of the New England Society of Psychiatry, American Psychiatric Association, Boston Medical History Club, Boston Society of Neurology and Psychiatry and the Massachusetts Psychiatric Society, assistant and first assistant physician, Worcester (Mass.) Insane Hospital from 1900 to 1905, neurologist on the staff of the Boston City Hospital from 1905 to 1919 and the Mount Sinai Hospital from 1905 to 1914, consulting neurologist to the Chelsea Memorial and Beth Israel hospitals from 1919 to 1928, neuropsychiatrist to Forsyth Dental Infirmary from 1913 to 1929, collaborating editor of the *Psychoanalytic Review* and the *Journal of Abnormal Psychology*, collaborator for psychoanalytic terms for Dictionary of Psychology, aged 67, died, May 26, of coronary thrombosis.

Isabella Coler Herb ⊕ Hubbard Woods, Ill., Northwestern University Woman's Medical School, Chicago, 1892, Secretary of the Section on Pathology and Physiology of the American Medical Association from 1915 to 1918 and chairman of the Section on Miscellaneous Topics from 1921 to 1924, retired on June 7, 1941 as head anesthetist of Presbyterian Hospital and clinical professor of surgery at Rush Medical College, continued her association with the hospital as anesthetist emerita, assisted Dr. Lawrence H. Primec, now of Kohn, Miss., in developing the open drop method of ether administration, later served on the staff of the Mayo Clinic, Rochester, Minn., for five years as anesthetist and pathologist, after further graduate study in Europe, carried on research in bacteriology under a grant from the American Medical Association and as an associate of Dr. Ludvig Hektoen, in 1909 gave up her work in pathology and started again to specialize as an anesthetist, joining the staffs of both Presbyterian Hospital and Rush Medical College, Chicago, the first woman appointed to the staff of Presbyterian Hospital and was the anesthetist who first administered ethylene gas at actual operations, author of chapters on anesthesia in several textbooks on surgery, aged 74, died, May 28, in the Presbyterian Hospital, Chicago, of heart disease.

Andrew Charles Smith, Portland, Ore., Cooper Medical College, San Francisco, 1877, Second Vice President in 1906, and a member of the House of Delegates of the American Medical Association in 1902 and 1909, member and past president of the Oregon State Medical Society, past president of the Portland Academy of Medicine and the Multnomah County Medical Society, fellow of the American College of Surgeons and chairman of the Oregon unit from 1928 to 1934, at one time assistant surgeon in the U S Army, first president and for twenty years active on the state board of health, formerly a member of the state senate and house of representatives, at one time associate in surgery at the University of Oregon Medical School, a member of the draft examining board during World War I, helped organize the Coffey Hospital, the county hospital and the Portland Open Air Sanitarium, on the staffs of the Good Samaritan and St. Vincent's hospitals, first president of the Medical Arts Building Company and the Oregon Good Roads Association, once president of the Hibernia Bank of Portland, aged 86, died, April 12, of bronchopneumonia.

Lida Stewart Cogill, Upper Darby, Pa., Woman's Medical College of Pennsylvania, Philadelphia, 1890, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, professor of obstetrics at her alma mater from 1923 to 1938 and since 1938 emerita professor, chief in obstetrics at the West Philadelphia Hospital for Women from 1906 to 1930, when it merged with the Woman's Hospital, Philadelphia, where she had been chief in obstetrics from 1930 to 1938 and on her retirement in the latter year became consultant in obstetrics, aged 74, died, April 18, of acute uremia.

Frank R. Borden ⊕ Lieutenant Colonel, U S Army, retired, Charlotte, N C., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois,

1902, Ph G, Northwestern University School of Pharmacy, Chicago, 1895, School of Aviation Medicine in 1942, served during World War I, commissioned a major in the medical corps of the U S Army in 1920 and retired in 1937 for disability in line of duty with the rank of lieutenant colonel, aged 68, died, March 28, in the Veterans Administration Facility, Augusta, Ga., of pneumonia.

Leo Chrysostom Mudd ⊕ Lieutenant Colonel, U S Army, retired, San Francisco, St. Louis University School of Medicine, 1907, Army Medical School, Washington, D C., 1911, commissioned a first lieutenant in the medical corps of the U S Army in 1911, became a captain in 1914, a major in 1917 and retired in 1918 for disability in line of duty, returned to active duty from Oct 5, 1918 to Feb 5, 1919, under a special act in 1930 was made a lieutenant colonel, served during World War I, aged 62, died recently of coronary thrombosis and pycnophritis.

Glenn Llewellyn Baker, Rib Lake, Wis., Northwestern University Medical School, Chicago, 1911, aged 58, died, April 11, in St. Joseph's Hospital, Marshfield, of chronic myocarditis and coronary thrombosis.

Stanley Walter Blazejewski ⊕ Wilkes-Barre, Pa., Baltimore Medical College, 1907, member of the surgical staff of the Hudson Coal Company, aged 63, a member of the staff of the Wilkes-Barre General Hospital, where he died, April 12, of coronary heart disease.

Dell Scotland Bowman, Akron, Ohio, University of Pennsylvania Department of Medicine, Philadelphia, 1893, past president of the Summit County Medical Society and vice president of the Ohio State Medical Association, for many years served as alienist for the Summit County Courts, formerly trustee of the Children's Home, visiting physician to the Edwin Shaw Sanatorium from Aug 1, 1915 to Sept 1, 1920, aged 79, on the staff of the City Hospital, where he died, April 18, of pneumonia.

Ola M. Buckman, Toledo, Ohio, Cleveland University of Medicine and Surgery, 1897, served on the staff of the Flower Hospital, aged 77, died, April 6, of carcinoma of the ovaries.

Charles Armstrong Byrne, Hatfield, Mass., Long Island College Hospital, Brooklyn, 1894, member of the Massachusetts Medical Society, aged 80, died, April 3, of bronchopneumonia and arteriosclerosis.

Robert Emmet Camfill, Springfield, Mass., Harvard Medical School, Boston, 1895, aged 70, for many years on the staff of the Mercy Hospital, where he died, April 7, of an appendical abscess.

William Stanley Carter ⊕ West Hazleton, Pa., Jefferson Medical College of Philadelphia, 1909, since 1938 trustee of the Hazleton (Pa.) State Hospital, West Hazleton borough school physician, physician for the Lehigh Valley Coal Company, organized a crippled children's society in 1924, aged 57, died, April 15, of heart disease.

Eugene George Charbonneau ⊕ East Orange, N J., Detroit College of Medicine, 1901, formerly served on the staff of St. James Hospital, Newark, aged 64, died, April 9, in St. Mary's Hospital, Orange, of heart disease.

Sylvan Coombs ⊕ Chicago, Rush Medical College, Chicago, 1891, fellow of the American College of Surgeons, on the staff of the Grant Hospital, formerly on the staffs of the Cook County, Henrotin and Columbus hospitals, aged 74, died, April 8, of carcinoma of the prostate.

James William Cox, Flomaton, Ala., Medical Department of Tulane University of Louisiana, New Orleans, 1895, aged 69, died, April 7.

William T. Craft, Brunswick, Neb., Omaha Medical College, 1902, aged 73, died, April 6, in Niobrara of heart disease.

William Clarke Craig, Ridgewood, N J., Jefferson Medical College of Philadelphia, 1907, served in the Medical Corps of the U S Army during World War I, a member of the New Jersey National Guard, on the staff of St. Joseph's Hospital Paterson, aged 58, died, April 12, of cirrhosis of the liver.

Albert Harlan Currie, Los Angeles, Bennett Medical College, Chicago, 1911, member of the California Medical Association, served as a captain in the medical corps of the U S Army during the World War, aged 56, died, April 19, of heart disease.

Arter Wayne Deal, Lewistown, Mont., College of Physicians and Surgeons, Baltimore, 1903, member of the Medical Association of Montana, formerly member and president of the Montana State Board of Medical Examiners, chief of staff of St. Joseph's Hospital, appointed surgeon to the Great Northern Railway in 1917, aged 61, died, March 13, of paralysis agitans.

James Harvey Donnelly Troy N Y Boston University School of Medicine 1897 member of the Medical Society of the State of New York, on the staff of the Samaritan Hospital aged 72 died April 8, of angina pectoris

Joseph Francis Doran Wilkesburg Pa, University of Pittsburgh School of Medicine, 1910 served during World War I aged 59, died April 12, of heart disease

Thomas Francis Dwyer, Buffalo, University of Buffalo School of Medicine 1885, aged 80 died April 11, in the Buffalo General Hospital of adenoma of the prostate, chronic uremia from bilateral pyelonephrosis and hemorrhagic cystitis

Charles Thomas Ehrnsberger, Lima Ohio, Miami Medical College Cincinnati, 1900 aged 70, died April 12 of coronary occlusion

David Paul Fry, Hedgesville W Va College of Physicians and Surgeons, Baltimore 1889 served on the staff of the City Hospital, Martinsburg aged 75 died April 14 of pneumonia

Willoughby Lyman Godfrey & Battle Creek Mich, University of Michigan Department of Medicine and Surgery Ann Arbor 1876 an Affiliate Fellow of the American Medical Association, past president and vice president of the Calhoun County Medical Society in 1928 the society presented him with a cup marked "Fifty Years in Medicine", aged 90 died, April 7, of arteriosclerotic heart disease

Raymond Weist Graham Syracuse N Y New York Homeopathic Medical College and Flower Hospital New York 1915 member of the Medical Society of the State of New York, aged 52 attending anesthetist and president of the staff of the Syracuse General Hospital, where he died April 4, of heart disease

Harold Louis Hall Brooklyn Cornell University Medical College New York 1910 member of the Medical Society of the State of New York aged 55 died April 6 in Tucson Ariz of coronary thrombosis

Charles C Hammond, Erie Pa, Medico-Chirurgical College of Philadelphia 1903 member of the Medical Society of the State of Pennsylvania served on the staff of the Adrian Hospital, Punxsutawney aged 64 died in April, of coronary sclerosis

Don Stuart Harvey & Chicago Rush Medical College Chicago, 1891 aged 75, served on the staff of the South Chicago Community Hospital where he died May 2, of lobar pneumonia and acute coronary insufficiency

Robert Hatfield Harvey, Chicago Northwestern University Medical School, Chicago 1894 aged 74, died April 29 of bronchopneumonia

Elnathan Pierce Hatheway, Ottawa Ill Rush Medical College Chicago, 1895 health officer of Ottawa on the staff of the Ryburn Memorial Hospital, aged 84, died April 4 of cerebral hemorrhage

Edwin Clyde Henry & Omaha, John A Creighton Medical College, Omaha, 1895, Medico-Chirurgical College of Philadelphia, 1896, past president of the Omaha-Douglas County Medical Society, served in France during World War I formerly chief surgeon and owner of the Lord Lister Hospital on the staffs of the Lutheran, Doctors and St. Joseph's hospitals past president of the Rotary Club aged 73 died, April 2 of cerebral thrombosis

Howard M Humphrey, Indianola Iowa State University of Iowa College of Homeopathic Medicine Iowa City 1895 aged 74 died, April 2 in Des Moines of cerebral hemorrhage

Carl Ireneus, Chicago National Medical University Chicago 1905 member of the Illinois State Medical Society at one time on the staff of the Washington Park Community Hospital aged 70 died, April 16 of acute coronary thrombosis

James Raymond Johnson, Philadelphia Howard University College of Medicine Washington D C 1919 served on the staff of the Mercy Hospital, examining physician for draft board number 9 aged 56, died April 6 of hypertensive cardiovascular renal disease

Francis Drake Kendall Sr, Columbia S C Medical College of the State of South Carolina, Charleston, 1883 served on the staff of the Roper Hospital Charleston for many years surgeon for the Southern Railroad aged 86, died April 4 of cardiovascular disease and asthma

George Lawrence Kessler & Brooklyn, New York University Medical College, New York, 1897 consultant to the Brooklyn Eye and Ear Hospital aged 74, died, April 3 of coronary thrombosis

William Benjamin Kunze Belleville, Ill St. Louis University School of Medicine 1906 aged 61 died April 1 in the Pleasant View Sanatorium, East St. Louis of tuberculosis

Isaac Herman Leion, Detroit University of St. Vladimir Faculty of Medicine Kiev Russia 1890 formerly a member of the Michigan State Tuberculosis Sanitarium Commission, served on the staffs of the Lincoln and Marr General Hospitals at one time medical examiner for the probate court of Wayne County aged 77 died April 8 of cerebral hemorrhage

William Vardeman Lindsay, Winona Minn Missouri Medical College, St. Louis 1898 member of the Minnesota State Medical Association past president of the Winona County Medical Society and the Winona County Public Health Association, served as a major with the American Expeditionary Forces in Siberia during World War I for many years health officer of Winona, in 1920 county physician aged 69, died, April 24, of coronary thrombosis

Francis W Mann, Wellington Mo Missouri Medical College St. Louis 1889, member of the Missouri State Medical Association aged 79 died March 11 of coronary occlusion

Robert Batten Mervine & Lock Haven Pa Jefferson Medical College of Philadelphia 1903 served on the staff of the Warren (Pa) General Hospital aged 62 died April 3 of cerebral hemorrhage

Robert J Montfort, Elizabeth, N J, University of the City of New York Medical Department 1890 member of the Medical Society of New Jersey served on the staff of the Elizabeth General Hospital aged 78 died April 4 of arteriosclerosis

Sampson James Morris, Chicago, Chicago College of Medicine and Surgery 1910 on the staffs of St. Mary's, Columbus and St. Elizabeth's hospitals a field health officer for the city health department aged 58, died, April 10, in Van Nuys, Calif of cerebral hemorrhage

Wallace Brown Perry & Lincoln Ill St. Louis University School of Medicine 1918 past president of the Logan County Medical Society on the staffs of the Evangelical Deaconess and St. Clara's hospitals aged 52 died April 9 of coronary thrombosis

Francis Herbert Poole & Major U S Army, retired Boulder Creek, Calif, Columbian University Medical Department Washington D C 1902 served during World War I became a major in the medical corps of the U S Army in 1920 and retired in 1933 for disability in line of duty formerly an agency physician in the U S Indian Service at one time medical superintendent of the Idaho Insane Asylum Blackfoot fellow of the American College of Surgeons aged 70 died recently of carbon monoxide poisoning

George Anthony Robertson Jr, Battle Creek, Mich University of Michigan Homeopathic Medical School Ann Arbor 1901 formerly on the staff of the Nichols Memorial Hospital aged 64 died, April 6 of acute uremia and carcinoma of the bladder

John Donald Target, Atlantic City N J University of Pennsylvania Department of Medicine Philadelphia 1898 member of the Medical Society of the State of Pennsylvania served in the U S Navy during World War I major in the medical reserve corps of the U S Army not on active duty aged 74 died April 13 of heart disease

DIED WHILE IN MILITARY SERVICE

Richard Davison Bullard & Saratoga Springs N Y Cornell University Medical College New York 1930 diplomate of the National Board of Medical Examiners fellow of the American College of Surgeons, an organizer and executive officer of the tumor clinic and member of the staff of the Saratoga Hospital at one time ship surgeon for the Grace Line the Panama Export Company and the American Export Company began active duty as a lieutenant commander in the U S Naval Reserve in July 1942 served on the U S S *Tasker H Bliss* which was lost off the coast of Morocco early in November 1942 aged 39 died April 22 in the Saratoga Hospital of carcinoma of the brain and pulmonary edema while on sick leave from the National Naval Medical Center Bethesda, Md

Frederick Paul Sedgwick, San Francisco University of Minnesota College of Medicine and Surgery Minneapolis 1941 began active duty as a first lieutenant in the medical reserve corps of the U S Army on Aug 6 1941 and later became a captain assigned to the 771st Military Police Battalion at Monterey, Calif. aged 29 died April 5 of a self-inflicted bullet wound

ORANGE JUICE SENSITIVITY IN BREAST FED INFANTS

To the Editor—This is a protest against the administration of orange juice to infants naturally fed. Scurvy is practically unknown in infants receiving human milk exclusively. The earlier researches indicated that breast milk was generally low in its ascorbic acid content, consequently the dictum that all infants should receive orange juice daily became incorporated in the dietary directions. Nearly every mother on leaving the hospital is directed to give her baby orange juice. The result is that an allergy to orange juice has become widely disseminated among infants. The fact that orange juice contains a soluble protein (about 1 per cent) is generally overlooked. This protein substance may readily be absorbed unchanged by the breast fed infant and, I believe, is the cause of this sensitization.

Moreover, human milk is approximately isotonic with the blood at the infant. The daily administration of orange juice supplies an excess of alkaline ions to be disposed of by metabolic and excretory processes and may lead to a hypertonicity and hyperexcitability.

Although I base my conclusion entirely on clinical experience, I am impelled to lay down this nutritional rule. The feeding of orange juice to breast fed infants under 4 months of age is contraindicated.

JOHN ZIMORSKY, M D, St. Louis

NOTE—From the point of view of the allergist the high permeability of the gastrointestinal tract of the infant in its first weeks of life must be emphasized (Lippard, V W, Schloss, O M, and Johnson, Priscilla A. Immune Reactions Induced in Infants by Intestinal Absorption of Incompletely Digested

Articles on Allergy in Breast Fed Infants

Hill, L W. Eczema in Infants and Young Children, *New England M J* 223: 624 (Oct 17) 1940.

Orange juice is likely to cause trouble in infants. Even if skin reactions are negative it is not uncommon for itching to be severe after ingestion of orange juice.

Rowe A D. Elimination Diets and Patient's Allergies.

Exclude all foods which commonly produce eczema or allergy, such as milk, eggs, wheat or orange.

Robinson, Edith C. Study of 240 Infants, *Am J Dis Child* 59: 1002 (May) 1940.

Fewer rashes in breast fed babies than in any other group.

Goodman, Herman and Burr, M E. Elimination Test Diets, *Arch Pediat* 54: 88 (Feb) 1937.

Some cases of eczema develop on breast feeding only. Usually the eruption occurs after complementary or supplementary feedings such as milk, orange juice and vegetables.

Hopkins, J G. Allergic Eczema, *Am J Dis Child* 49: 1511 (June) 1935.

Of various foods found to be the sole cause of eczema in infants as proved by the elimination of such foods, eggs were found to cause trouble in one half of the cases, wheat and milk in about one fourth of the cases, oranges next, then spinach, potatoes and so on. For example:

	No of Cases	Positive Skin Reactions	Allergic Reaction After Eating Food
Egg	43	32	35
Wheat	26	12	21
Milk (cow)	19	12	18
Orange	6	4	6

Cow's Milk Protein, *Am J Dis Child* 51: 562 [March] 1936). Because of this it seems to be advisable that the diet of the infant with an allergic disposition should be as simple as possible. If human milk is available in adequate amounts for good nutrition, it would be advisable to delay adding any other food for several months. However, this need not apply to all infants.

Only about 10 per cent of the population develops any allergy. It is also generally accepted that allergy developing in infants is usually associated with a family history of allergy. It would therefore appear to be more reasonable that any limitation in diet should be directed only to those children who give a family history of allergy. Even here, allergists are inclined to avoid any special precaution as far as diet is concerned except the advice to add only one food at a time during the first year of life to avoid food mixtures and to look for the causes of skin rashes or gastrointestinal disturbances with the possibility of allergy in mind. The pediatrician or the intelligent mother who is watchful for symptoms suggestive of allergy will recognize the first signs of it, and serious trouble may almost invariably be avoided by rapid recognition of the offending agent and the elimination of the cause.

In other words, there is too great a tendency "to be allergic conscious" and to lay down special rules other than those of careful observation.

Accompanying is a list of articles regarding the frequency of orange juice as a cause of symptoms of allergy, and of the frequency of allergy in breast fed infants.

BEN Z. RAPPAPORT, M D, Chicago

RING TEST IN VAN DEN BERGH REACTION

To the Editor—Referring to the use of the term "the ring test of Lepehne" in the paper "The Functional Value of the Liver in Heart Disease" by Chavez, Sepulveda and Ortega I (*THE JOURNAL*, April 17), Lepehne, now working at Boston University School of Medicine, is not responsible for the application of the ring technic now used so extensively in the performance of the van den Bergh reaction ("direct" reaction). In an editorial in the *Journal of Laboratory and Clinical Medicine* a decade ago Magath did give Lepehne credit for the test, remarking that it was "rediscovered by Elton ten years later," but examination of Lepehne's report showed that while he tried overlaying the diazo reagent on serum rather than mixing it before I did, he did not appreciate its clinical value and stated that it afforded no advantage over the original technic. I believe I was the first (quite accidentally) to find that this method sensitized the van den Bergh reaction tremendously in detecting the presence of bilirubinate ("direct" reacting form) in blood serum, and I have made a number of studies based on that observation, leading to my own conceptions of the mechanism of jaundice in general, which seem to have been acceptable to the authors of a number of textbooks on clinical pathology.

Some time ago, with the help of Mr Kalmar, I translated van den Bergh's monograph "Der Gallenfarbstoff im Blut," ed 2 (1928), "nahezu unveranderte," and noted that he was well aware of the positivity of the (direct) reaction (even without the ring technic) in congestive heart failure. His first edition, containing this and many other significant observations for which he has not been accorded full credit, was published in 1918. The publication of his monograph in English would be a contribution to the classics of scientific literature, but one's blood pressure has to be taken into consideration in such effort and thus far I have been quite successful in keeping mine down where it should be.

It is my earnest hope that Hijmans van den Bergh will survive the Nazi occupation of the Netherlands and reassume his position of leadership in medical science.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Pregnancy Mistaken for Fibroid Tumor—The plaintiff, a woman aged 37 who had borne five children, consulted the physician defendant on June 25, 1938. According to the patient and her husband who accompanied her, she told the physician that she was pregnant and that she had not menstruated since the preceding October. The physician and his office nurse, however, testified that he interrogated the patient concerning menstruating and both she and her husband said that is just the point. She has gotten to the point where she is unable to do her work from which the physician inferred that she had been bleeding too much. Also according to the physician and the nurse, when the possibility of pregnancy was broached to her, she replied, "Doctor, that is impossible. I am the mother of five children and if I was in the family way I would certainly know it." The physician then made a bimanual or vaginal examination of the patient and concluded that she had a fibroid tumor. Accordingly on July 6 he performed an operation to remove the supposed tumor and discovered that the plaintiff was pregnant. Nine days later the patient was delivered of a dead fetus fully developed. Subsequently she sued the physician and the hospital in which the operation had been performed for malpractice. At the conclusion of the plaintiff's evidence the hospital was dismissed, and at the close of the case the jury returned a verdict in favor of the physician and judgment was entered thereon. The circuit court of Kanawha County, West Virginia, on appeal, reversed the judgment in favor of the physician and ordered a new trial and the physician appealed to the Supreme Court of Appeals of West Virginia.

The trial court admitted testimony concerning the physician's reputation for skill and care. This the patient contended with which contention the circuit court agreed, was erroneous because of the general rule in cases of malpractice that evidence of the defendant physician's reputation in the community and among his profession as to skill and care is inadmissible unless questioned by the plaintiff. The physician, however, cited *Dudley v. Grace Hospital*, 112 W. Va. 461, 164 S. E. 670, as decisive of the admissibility of such evidence. In that case it was held that in an action for malpractice where the declaration charges want of skill and care generally and does not limit the charge to a specific act, evidence of the physician's reputation for skill and care is admissible. In that case the defendant had undertaken to perform a tonsillectomy on the patient, and the declaration charged that by and through their want of skill and care in some way or by some means without the knowledge of plaintiff and beyond her power to explain, caused an injury to plaintiff's left eye. The court there expressed the opinion that the language used in the declaration did not limit the want of skill and care to any particular act and held that it was a direct charge on the defendant's proficiency generally and therefore the physician's reputation for skillfulness and care became a proper inquiry for such consideration as the jury deems requisite. In this case, however, said the Supreme Court of Appeals, the sole reference in the declaration filed by the plaintiff relating to the skill of the physician defendant was a charge that the physician unskillfully attempted to stitch the wound. In the first place, such an allegation relates to a specific act and therefore does not fall within the rule propounded in the *Dudley* case. Moreover, we do not believe that such an allegation is one which charges a lack of skill or ability on the part of the operating physician to stitch the wound but rather a careless performance. Exclusive of such allegation, the gravamen of the declaration is definitely one of negligence and therefore,

the general rule as relied on by the patient is applicable and the admission of evidence relating to the physician's reputation for skill and care in the community and among his profession was erroneous.

The Supreme Court of Appeals accordingly remanded the case to the trial court for a new trial—*Robinson v. Amick*, 21 S. E. (2d) 161 (W. Va., 1913).

Workmen's Compensation Acts Cerebral Hemorrhage Precipitated by Strain of Employment—The claimant at the time of the alleged industrial accident was a man of about 75 years of age and had arteriosclerosis and hypertension. He had worked for a number of years as a glue cooker for the defendant employer. The "glue room" in which he worked was reached by ascending two perpendicular ladders of about 12 feet and 8 feet, respectively. It was his duty to pull sacks of glue weighing from 100 to 200 pounds by rope and pulley to the "glue room," to stack these sacks and as needed to weigh them and dump the contents into "cooking" kettles. On the day of the alleged industrial accident, the "glue room" was unusually hot and the claimant did "all he could do." After working for about three and a half hours he descended the ladders for a drink of water. Just as he reached the main floor he felt a roaring sound in his left ear and had a dead or numb feeling in his right arm and leg. He was able to return to the "glue room" with difficulty but continued on the job, doing light work. About four and a half hours later he began to feel worse and could not hold a pencil in his hand to execute a daily report. He quit work, and just as he reached the main floor his right side "gave way" and he was taken home in a semiconscious condition. Subsequently a diagnosis of cerebral hemorrhage was made and the workman became partially paralyzed on his right side. He brought proceedings under the workmen's compensation act of Louisiana. From a judgment in his favor the employer appealed to the Court of Appeals of Louisiana, first circuit.

The principal question in this case, said the court, involves both one of fact and one of law—of fact, as to whether or not the claimant suffered an accident which was a contributing cause of the rupture of a cerebral artery, and of law, "as to whether or not there was any accident and causal connection between the alleged injury and the present disability," within the meaning of the workmen's compensation act. The claimant's attending physician testified that the claimant had hardening of the arteries and that this condition, coupled with the physical exertion and overheating in connection with his work, caused his blood pressure to rise, producing a rupture of the cerebral artery. Another physician, who was called in consultation in the treatment of the claimant, testified that the hardening of the arteries present in the claimant was not caused by any overexertion or overheating but that a person with hardening of the arteries and high blood pressure could by undue physical and mental exertion cause the blood pressure to rise temporarily, putting a greater strain on the brittle or weakened arteries and thus produce a rupture and resulting hemorrhage. In this physician's opinion the exertion and overheating of the claimant while working combined with his condition to cause the cerebral hemorrhage, which was the cause of his present disability. Two physicians called by the employer stated that the strain and exertion put forth by the plaintiff while at work had no causal connection with the cerebral hemorrhage but that it was a mere coincidence that the hemorrhage occurred while the claimant was on the job and that it might just as likely have occurred while he was straining at stool or doing almost anything else off the job. The trial court called three physicians as court witnesses. Two of these physicians testified that the exertion and overheating had no causal connection with the hemorrhage because the hemorrhage did not occur at the height of the exertion. The other physician, however, believed that the exertion and overheating did precipitate the hemorrhage, that the elevation of blood pressure caused from lifting and handling the sacks continued and persisted while the claimant was descending the ladders.

The medical evidence, continued the court, indicates that a warm temperature does not tend to increase the blood pressure but rather has the opposite effect. However, the sudden lowering of the temperature does have the effect of raising the blood pressure. According to the evidence, blood pressure will subside in a very few minutes after the exertion ceases. Because of this, the employer contended that any elevation in the claimant's blood pressure caused from his overexertion in the "glue room" would have subsided before he reached the bottom of the ladders. However, said the court, as one of the physician witnesses called by the court testified and as the other physicians in the case admitted, climbing down these two steep ladders a distance of 20 feet is considerable exercise in itself. In fact, it would seem that for a man of the claimant's age climbing down these ladders required about as much physical exertion as did the performance of his duties in the "glue room." We conclude that the strain and exertion put forth by the claimant for several hours in handling the heavy sacks in the hot "glue room" caused his blood pressure to rise, that the continued exercise in descending the ladders and becoming exposed to the cooler air kept the blood pressure elevated and that when the claimant reached the floor this continued, and persistent pressure on the brittle and weakened cerebral artery caused it to rupture. The situation is similar to an automobile tire with worn fibers and blisters in the rubber when the air pressure is such as to bring the walls of the tire to the breaking point. The tire might hold up with this pressure for a while, but the continued strain will finally cause it to blow out.

During each systole, continued the court, the ventricles of the heart force blood into the arteries that are already full. The extensibility of the arteries enables them to distend and receive the extra supply of blood. When the systole is over and the force is relaxed, the elasticity of the arteries causes them to recoil to their former diameter in a normally healthy person but as the result of age, or other cause, the walls of the arteries may become less elastic and then do not properly perform their function. This condition is called arteriosclerosis, and any increase of the blood pressure against the worn out arteries is likely to cause a rupture. If the exertion and straining in working cause such an elevation in the blood pressure of a person with hardened arteries as to cause the artery to rupture and result in a hemorrhage, this is an injury to the physical structure of the body and is such an unexpected and unforeseen occurrence as to constitute an accident within the meaning of the workmen's compensation law.

While the claimant was performing his work in the usual and customary way, it was apparent that this work on the day of the industrial accident was unusually heavy and that the "glue room" was unusually warm. To a person with hardening of the arteries and high blood pressure, hard work is more or less pulling the trigger on a cerebral hemorrhage. To argue that the claimant might have had the stroke while off duty is merely to indulge in speculation. The fact is that the claimant did not have the hemorrhage while off duty, but the hemorrhage occurred in the course of his employment and was precipitated by the elevation of the blood pressure produced by the lifting, exertion and straining incurred in connection with his work.

The court accordingly concluded that the claimant had suffered an accident, within the meaning of the compensation act, which was a contributing cause to the rupture of his cerebral artery and that there was a causal connection between the industrial injury and the present disability. Accordingly the award of compensation in favor of the workman was affirmed.—*Murray v. Mengel Co*, 9 So. (2d) 818 (La., 1942).

Placental Transmission of Sulfathiazole and Sulfadiazine.—Organisms most frequently encountered in severe neonatal infections are among the most responsive to sulfonamides. Speert investigated placental transmission of the sulfonamide compounds with the view of extending their scope in fetal prophylaxis and intrauterine therapy. He observed that sulfathiazole and sulfadiazine, like sulfanilamide, diffuse readily across the placenta. A single intravenous dose of 5 Gm of sodium sulfathiazole or sodium sulfadiazine to the mother during labor causes the drug to appear in the fetal blood almost immediately. They are retained there in therapeutically effective concentrations for at least six hours in the case of sulfathiazole and considerably longer in the case of sulfadiazine. Equilibrium between maternal and fetal blood is established within three hours. A higher concentration of sodium sulfadiazine is obtainable in the fetal blood than is possible with an equal dose of sulfathiazole. These drugs also appear in the amniotic fluid, but later than in the fetal blood. The intravenous injection of sodium sulfathiazole or sulfadiazine into the mother is suggested as a method of treating the fetus in utero in cases of intercurrent or intrapartum infection caused by susceptible organisms. When the lower part of the mother's genital tract harbors the gonococcus the establishment of an adequate sulfathiazole or sulfadiazine concentration in the fetus prior to delivery would appear indicated as a prophylactic measure.

Colostrum Intradermal Test for Diagnosis of Pregnancy.—The colostrum intradermal test of Falls, Freda and Cohen for the diagnosis of pregnancy was used by Allen and Donaldson in 151 known pregnant and 81 known nonpregnant women. The reaction of the test was correct in 82 of the first group and in 28 of 38 of the group in the first trimester. The percentage of accuracy for the second group is 87.65 or in 71 of the 81 women known not to be pregnant. Allen and Donaldson point out that the percentage of accuracy in their series of pregnant and nonpregnant women is much lower than that obtained by the original investigators. There seems to be either

a difference in potency in individual colostrum samples or a periodic change in individual sensitivity. Cutaneous sensitivity appears to play a part in false or incorrect reactions. More work should be done on the hormone content of colostrum.

Importance of Rh Blood Factor in Erythroblastosis.—During the last several years Potter, Davidsohn and Crunden examined many fetuses and infants at necropsy. Following the discovery of the Rh blood factor they attempted to obtain blood from the women who had given birth to the infants and fetuses presenting any suggestion of erythroblastosis as the cause of death. The blood of 60 mothers giving birth to babies with erythroblastosis and of 59 infants and fetuses has been tested. Only 6 of the infants were Rh—. When the mother is Rh— and the father is Rh+ either 50 or 100 per cent of the offspring will be Rh positive, the difference in percentage depending on whether the Rh factor in the father is homozygous or heterozygous. If fetal blood containing the Rh factor gains access to the maternal circulation, agglutinins may be produced in the mother's blood. When it is necessary to transfuse an infant with erythroblastosis the mother's blood should never be used. The authors have not observed free anti Rh agglutinins in the blood stream of such infants nor have they found such a record. Therefore they question whether it is necessary to transfuse with Rh negative blood on this basis. If the cells and the serum of a patient and a potential donor do not agglutinate after incubation at 37 C for one hour and centrifugation at 600 revolutions for one minute the blood of this donor can be used with safety regardless of whether it is Rh positive or negative. As the majority of women who bear babies with erythroblastosis are known to be Rh negative and may show anti Rh agglutinins it is essential to use blood from a known Rh negative donor if transfusion becomes necessary in such a woman. Since the Rh factor is present in approximately 86 per cent of the population, about 12 per cent of marriages will be between an Rh negative wife and an Rh positive husband. Such a wife is capable of becoming sensitized to the Rh factor and of subsequently reacting on the fetus to produce erythroblastosis. However, erythroblastosis in the authors' experience has been found in only about 0.1 per cent of all pregnancies. The several conditions which may account for the difference between the potential and the actual incidence are childless or one child marriages, the ability of the Rh antigen in the infant to stimulate the production of agglutinins in the maternal blood, the probable variable ability of the placenta to prevent the passage of the Rh antigen, the probable variance of the maternal response to the Rh antigen into the blood stream and the probable variable ability of the placenta to permit passage of agglutinins. Apparently other superimposed factors are operative in the determination of whether or not erythroblastosis will be realized. A few women giving birth to babies who appear to have erythroblastosis are Rh positive and a few such infants are Rh negative. Therefore it may be possible that these infants are actually suffering from a different disease entity. However, a doubtful diagnosis of erythroblastosis can be confirmed by finding the maternal blood Rh negative and the paternal and infant blood Rh positive. If the mother is Rh positive, the diagnosis of erythroblastosis is less probable.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

VIRUS PNEUMONIA OR UNUSUAL ARSENICAL REACTION

To the Editor—During the past year I have encountered two identical syndromes which can be classified by me only as "atypical pneumonia," and even this flexible term leaves much to doubt. Briefly, two employees of the sanatorium—one a Negro maid and the other a Negro nurse, the former found to have a positive serologic reaction for syphilis and a history of inadequate therapy, and the latter picked up with typical secondaries and a positive serologic reaction—were started with neoarsphenamine injections. In both cases after the fifth and seventh injections (0.45 Gm) respectively there was a subacute illness characterized by cough, dyspnea and mild elevation of temperature. There were scattered rales over the majority of both lung fields, with areas of suppressed breath sounds and others in which there was bronchial character to the breath sounds suggestive of severe bronchopneumonia. However, neither of the patients appeared acutely ill. The most striking feature was the x-ray examination, which revealed diffuse soft shadows over both lung fields, being lightest in the extreme apices, and in 1 case areas of rarefaction resembling cavitation. Numerous sputum examinations were negative for tubercle bacilli, and serial films showed gradual clearing on bed rest, so that over a period of approximately five months there was complete resolution of the shadows. In each case the x-ray examination of the chest had been completely negative within a few weeks of beginning arsenotherapy. There was nothing significant in routine blood counts and urinalysis, and the sedimentation rate was only moderately accelerated in both cases, showing improvement with clearing of the lungs. In summarizing, the following factors in both cases do not fit my present conception of virus or atypical pneumonia: the onset gradually of cough and dyspnea early in the course of arsenotherapy, the diffuse involvement of the lungs and the benign but prolonged course before clearing of pulmonary shadows. I should like to know if there is a possibility of this syndrome being a reaction to the neoarsphenamine. The nurse has been returned to employment here at the sanatorium and at present is receiving bismuth subsalicylate, which is tolerated well. I shall appreciate any suggestions as to the future precautions in regard to further use of neoarsphenamine in her case.

M D, South Carolina

ANSWER—There is a possibility that the syndrome may be the result of a reaction to neoarsphenamine, but the cases described are unusual indeed. Reactions to arsenobenzenes are classified as immediate or delayed and the cases in question would be included among the latter. A variety of disturbances may develop after neoarsphenamine therapy, involving the skin, the liver, the heart, the gastrointestinal tract and the nervous system, but little or no mention is made of pulmonary reactions.

In one article (Wright, C. S. Syphilis, in the *Cyclopedia of Medicine*, 1940, vol 14, p 745) it is stated that "another unfavorable symptom is the development of a bronchiopneumonia." The pneumonia which occurs, however, usually accompanies severe exfoliative dermatitis (apparently absent in the cases referred to) and may be incited by a similar exfoliative process of the lining of the pulmonary air passages. Syphilitic pneumonia has been described but is apparently not to be considered in the present discussion.

On the other hand, it is also possible that both patients had atypical or virus pneumonia. The points which the questioner raises against this diagnosis do not rule it out. There is no reason why patients receiving any form of therapy cannot develop pneumonia, the involvement of the lungs in virus pneumonias may be diffuse, and the pulmonary shadows may persist for long periods.

There are no rules whereby one may predict future recurrences of reactions after arsphenamine therapy, except that if a patient reacts unfavorably once he is apt to do so again. According to the advice of Robinson (*The Resumption of Antisyphilitic Therapy Following Postarsphenamine Reactions*, *Pennsylvania M J* 46 667 [April] 1943) continued therapy seems advisable in the case of the nurse, if the severity of the reaction did not outweigh the importance of treatment in an early case. Perhaps the substitution of an arsenoxide drug such as mapharsen would be desirable. On the other hand, regardless of the type or degree of syphilis, when blood dyscrasias, exfoliative dermatitides or involvement of the nervous system results from therapy, resumption of treatment with arsenical compounds should not be considered.

INHERITANCE OF RETINITIS PIGMENTOSA

To the Editor—If a man has retinitis pigmentosa and is married, should the wife be advised not to have children and, if not, should such a case be grounds for performing a therapeutic abortion? The man is 30 years of age.

M D, New York

ANSWER—There has been a good deal of discussion about the question of prevention of childbirth in patients with retinitis pigmentosa. The conclusions seem justified that, since retinitis pigmentosa is recessively inherited, the chance of its being transmitted to the offspring of one affected person is slight or, in fact, almost impossible. It is stated that the only way in which cases of retinitis pigmentosa can occur is by a union between an affected person and a nonaffected person who is a member of a family that is affected with retinitis pigmentosa. Thus may be the case even though no known cases can be traced in the family. The chances of trouble are so remote that the couple in question probably need not refrain from having children and a therapeutic abortion would not be indicated.

EXPRESSING QUANTITY OF ROENTGEN IRRADIATION

To the Editor—In x-ray therapy how is the roentgen estimated? For example, how would such a dose as the following be expressed 5 ma., 86 Kvp, at 8 inch distance for one minute?

N S Fraser, M D, St John's, Newfoundland

ANSWER—The quantity of irradiation given is measured in roentgens. The most satisfactory and simplest instrument is the electroscope with an ionization chamber attached. The ionization chamber is placed in the direct x-ray beam. Readings are taken either in air or on the skin. Higher readings will be obtained with the ionization chamber on the skin, as the result of "backscattering" of the rays. It is necessary when recording dosage to specify whether the readings were taken in air or on the skin. The lower the kilovoltage, the greater the "backscattering."

Example: 5 milliamperes, 86 kilovolt peak, at 8 inches target skin distance, no filter added. Roentgens measured in air. Half value layer: this is the amount of the specified material (usually aluminum at lower voltages) necessary to reduce the intensity (roentgens) of the beam of x-rays to one half of its initial value.

ETIOLOGY OF GANGLIONS

To the Editor—Will you please inform me of the current opinion relative to the etiology of simple ganglions (cystic tumors in tendon sheaths). I am especially interested in knowing whether or not trauma (either single or repeated) is believed to be an etiologic factor in their development.

A L Kefauver, M D, Columbus, Ohio

ANSWER—The etiology of ganglions is still not clear. The best judgment is that they result from a low grade inflammatory process developing within the joint capsule or over the periosteum of the small bones about the wrist. They have no relationship to the sheaths of the tendons, as is often suggested, except proximity. That misconception is responsible for the fact that incomplete removal is common and invariably followed by recurrence.

There is no definite evidence that trauma is a factor in the development of this condition.

LEFT HANDEDNESS

To the Editor—A girl aged 3 years prefers using her left hand when eating and writing. Should I advise her parents to encourage her to use her right hand, in view of the fact that this is a right handed world? At this age, in my opinion, it is difficult to determine the predominant hand definitely. Does it cause any ill effects to make her right handed?

Bernard S Dignam, M D, Thompsonville, Conn

ANSWER—The parents should encourage the child to use the right hand in eating, since this is the only situation that occasions social embarrassment. Ill effects may follow if a predominantly left handed child is forced to use the right hand. The development of finer coordinations in general tends to be interfered with.

DENTAL INFECTIONS AND URINARY INFECTIONS

To the Editor—Are infections about the teeth considered one of the sources of infected (surgical) kidney? I am informed that this opinion is now obsolete and untrue.

M D, California

ANSWER—Infections about the teeth are definitely considered the source for infected kidneys of any type. There is nothing especially characteristic about this type of infection that would make it surgical but any kidney infection, under proper conditions, may become subject to surgery.

It is a general procedure in the urologic clinics of the country to search for distant foci and eradicate them in the presence of upper urinary tract infections of any sort.

THE LABORATORY DIAGNOSIS OF VIRUS DISEASES

S EDWARD SULKIN, PH D
AND
CARL G HARFORD MD
ST LOUIS

Perhaps at no time in the history of medicine has such an era of discovery and adaptation of knowledge occurred as in the past two decades. This is especially noteworthy in the case of virus diseases. Although these ultramicroscopic agents have been known to exist for many years, knowledge of their specific properties has been elucidated only in recent years. During this time the study of viruses has grown into a branch of medical science equal in importance to bacteriology itself. This development has been so recent and the literature has grown so rapidly that there are few sources from which the clinician or the laboratory worker can obtain a simple and adequate survey of the present status of knowledge pertaining to methods of diagnosis of virus diseases. Actually it seems unlikely that the diagnosis of virus diseases will ever attain the simplicity of the diagnosis of bacterial infections. Furthermore controversies have arisen in numerous instances as to the most practical methods of laboratory diagnosis. In many instances one method has been accepted as most valuable, while in the diagnosis of other diseases several tests are available.

The clinical features of certain of the virus diseases are uniformly consistent permitting the physician to make a diagnosis with a fair degree of regularity. However it should not be concluded that all virus diseases can be diagnosed without the aid of certain laboratory procedures. This is especially true of virus diseases of the central nervous system. In attempting to establish an etiologic diagnosis of some of the human encephalides the clinician has had to depend on methods that are either inadequate or else cannot be adapted as a routine laboratory procedure. Also the laboratory may be of aid in the diagnosis of various abortive infections of virus origin.

Our primary objective in this article is to provide the physician as well as the laboratory worker with an analysis of acceptable procedures that are now available. Furthermore the discussion is limited to an account of only those diseases of man in which it is generally accepted that the causal agent comes within the virus category.

The procedures followed in the laboratory diagnosis of virus diseases are analogous to those used in bacterial infections. Conclusive evidence consists in the demonstration and identification of the virus, although such tests are tedious and expensive. This may be readily accomplished in some of the virus diseases (psittacosis, yellow fever, influenza and rabies) by using susceptible laboratory animals or chick embryos instead of the ordinary culture mediums used for the isolation of bacteria. Unfortunately many factors complicate the use of certain animals in virus study: (1) costliness of animals prohibits their use (monkeys in poliomyelitis); (2) in some cases animals must be strictly isolated to prevent contact infections (ferrets in influenza); and (3) latent viruses of ordinary laboratory animals frequently confuse diagnosis.

Once the virus is recovered, identification is accomplished by determination of the animals for which it is pathogenic, routes by which it can be given, tissues which it infects, pathologic lesions produced (including inclusion bodies) and specific immunologic reactions.

In the diagnosis of bacterial diseases it is often useful to cultivate the causative organism from lesions or discharges. Since viruses cannot be grown in the absence of living cells it is necessary to inoculate animals with material from the patient. The route chosen for inoculation usually depends on which tissues of the body are susceptible, for example in influenza secretions from the human respiratory tract are inoculated intranasally into ferrets. Evidence that a virus is present is demonstrated by the production of a disease in the animals inoculated. This may be recognized by clinical and pathologic signs. The disease should then be transmissible similarly from animal to animal indicating that a true infectious agent is present. Cultures, smears or sections may be employed to determine that bacteria or other nonviral infectious agents are not producing the lesions.

After the identification of a virus it is important to determine whether it was present in the body as an incidental contaminant or whether it was similarly encountered during passages in animals. Comparisons of the clinical and pathologic aspects of the disease in human beings and in animals help to determine this point. The comparison of immunologic tests on serums taken during the acute phase and convalescent stages of disease in human beings is likewise important. If specific antibodies have developed during or shortly after the clinical disease it is likely that the virus is the cause of the human disease.

Microscopic study of virus-containing tissues is of value in identification and in establishing the relationship of the virus to the human disease under investigation. Certain viruses producing apparently identical lesions however may be distinguished only by their species specificity or their immunologic reactions. Inclu-

From the Virus Laboratory of the St. Louis Health Division and Department of Bacteriology, Washington University School of Medicine. Owing to lack of space this article has been abbreviated for publication in THE JOURNAL by omission of the bibliography (to which the superior figures in the text refer). The footnotes to the table are presented in abbreviated form. The complete article appears in the authors' reprint.

sion bodies are not sufficiently distinct in all cases from the morphologic standpoint to serve as characteristic indicators of the presence of virus. Furthermore, these bodies have not been demonstrated in a number of virus diseases, they have been found often in pathologic material in which the presence of a virus could only be suspected¹ and they have been produced in tissues in which the presence of a virus could be excluded with reasonable certainty. When a virus can be demonstrated by passage as indicated previously, the presence of inclusion bodies may serve as corroborative evidence.

NEUTRALIZATION TESTS

Neutralization tests are generally used for detecting the presence of virus-neutralizing antibodies for diagnostic or epidemiologic purposes. The serum to be tested is mixed with the virus in suitable proportions and then inoculated into susceptible animals. In some of these tests the amount of virus used is kept constant and different dilutions of serum are added, while in others the amount of serum is kept constant and the virus diluted. In general, the basis on which virus neutralization tests are interpreted depends on the susceptibility of the animal used. Usually when the virus is highly pathogenic the results are interpreted according to the proportion of animals that survive. When a less infective virus is used, all animals that do not die must be killed and examined for evidence of specific lesions. For example, in the case of neutralization tests with influenza virus, the lungs of all mice are usually examined for evidence of consolidation.

It has been shown that demonstration of protective antibodies is more effective when serum-virus mixtures are given by some routes of inoculation than by others.² This fact must be taken into consideration when practical diagnostic tests are being done. For example, with vaccinia virus, neutralization is more readily demonstrated if serum-virus mixtures are inoculated intracutaneously rather than intratesticularly in the rabbit. In equine encephalomyelitis it is preferable to inoculate 16 day old mice intra-abdominally rather than intracerebrally.

The most conclusive diagnostic evidence is available when the virus has been recovered from infectious tissues and an increase in specific neutralizing or complement fixing antibodies demonstrated in the convalescent serum of the patient. Correlation of laboratory and clinical findings in certain virus diseases, however, has shown that the serologic procedures are applicable even when virus is not recovered. Immunologic tests should be done on the blood serum obtained during the early stages of the disease and again after recovery of the patient. The presence of specific antibodies is of particular significance if blood specimens taken during the acute phase are negative and become positive with convalescence of the individual. Though such diagnoses can be made only after the patient recovers from the disease, they are of definite public health significance. Frequently a specimen of serum can be obtained only during convalescence. In such cases the validity of the diagnosis depends on the frequency with which serums from apparently normal persons in a given community give positive tests. For example, in attempting a diagnosis of St. Louis encephalitis or lymphocytic choriomeningitis by single specimens of serum taken during convalescence, it must be remembered that the serums of many normal persons of the same community also give positive results.⁴ During epidemic periods,

because of subclinical exposure, a large percentage of normal persons may develop antibodies against the virus responsible for the outbreak. Accordingly, based on the study of serum specimens from the general population and from cases of influenza occurring during the 1940-1941 outbreak in St. Louis,⁵ the level of complement fixing antibodies near a titer of 1 to 16 in terms of the original dilution of the patient's serum was found to be significant of epidemic influenza. In certain virus diseases specific antibodies develop quite rapidly (St. Louis encephalitis and equine encephalomyelitis), while in others antibodies may not become apparent for several weeks or even months (lymphocytic choriomeningitis). The absence of neutralizing antibodies against at least the poliomyelitis virus in human serum may not exclude the diagnosis, since specific antibodies may not develop in the serum after a typical clinical attack.⁶ On the other hand, the disease may develop in persons who already possess antibodies in their serum. Although it is possible that these facts may be explained when there is more knowledge of immunologically distinct strains and inapparent infection, it now appears that serologic tests alone are of little value in the diagnosis of poliomyelitis.

Specific neutralization tests have been described for many of the known virus diseases, and the accompanying table indicates where these tests may be of value as laboratory aids in diagnosis.

IN VITRO TESTS

The early literature contained many conflicting reports concerning the application of complement fixation tests to the study of virus diseases. In subsequent years, however, various improvements have been introduced which have resulted in the more extensive use of this test. Various workers have shown that some anti-viral serums are capable of fixing complement in the presence of their homologous antigens similar to the fixation of complement by antibacterial serums with suspensions of the appropriate micro-organisms. The essential difference, however, lies in the fact that viruses cannot be grown in large amounts on ordinary culture mediums and that antigen consisting of infected tissues must be employed instead. This necessitates the addition of suitable antigen and serum controls. Theoretically, in vitro immunologic reactions should be demonstrable, provided a sufficient quantity of virus is contained in the tissue used as antigen.⁷ However, if the concentration of virus in the tissues is low, a delicately balanced system must be used.¹⁴ Enough time must be allowed for the union of antigen and antibody. Accordingly, Bedson and Bland¹⁷ permitted complement fixation to occur over a period of hours at low temperature, employing the procedure previously used for increasing the delicacy of the Wassermann test.

Although many investigators doubted the specificity of the early complement fixation tests with viruses, sufficient evidence has accumulated in recent years to eliminate uncertainty. Virus diseases that can now be diagnosed by means of the complement fixation test, together with the respective authorities, are indicated in the table. The reader is referred to the articles cited for details of technique of tests.

Precipitation or flocculation reactions have been reported by many investigators.¹⁸ The practicability of these precipitation tests as a diagnostic aid in the diagnosis of virus diseases is limited, as indicated in the table.

THE USE OF THE CHICK EMBRYO AS AN AID IN DIAGNOSIS

The chick embryo is now widely used for the isolation, cultivation and titration of viruses for titration of antiviral serums. It is a source of antigen for immunologic procedures for the preparation of vaccines for human use and for studying the development of lesions. The reader is referred to the articles by Goodpasture and his associates,³ Burnett,¹⁰⁰ Stevenson and Butler,¹⁰¹ and Bengtson and Davi,¹⁰² for details of methods now in general use for inoculating eggs. Convenient histologic methods of examining infected chorioallantoic membranes have been described by Goodpasture and his co-workers,¹⁰³ Himmelweit,¹⁰⁴ and more recently Burnett and Faris,¹⁰⁵ Cooke and Blattner,¹⁰⁶ have described a method for supravital staining which renders lesions on the membranes more easily visible.

PRESERVATION OF VIRUSES

It has long been known that viruses which are unstable and rapidly become inactivated at room temperatures retain their infectivity for longer periods at lower temperatures. Even the most unstable viruses may be stored almost indefinitely with no detectable decrease in infectivity when maintained at low temperatures. Proper preservation of viruses eliminates the necessity of expensive and time consuming animal passage and is important if virus is to be available when needed. The most widely used method of preservation consists of the immersion of infected tissue in glycerin (It is not necessary to use the Schering-Kahlbaum brand of glycerin, but it is desirable to use a good pure grade.) This method is simple but does not maintain the infectivity of some viruses over long periods. Flossdorf and Mudd¹⁰⁷ have described procedures and apparatus for preservation of viruses and other biologic materials by drying while in the frozen state. This system has been found to be very effective for most viruses. Carbon dioxide in solid form has been used to maintain virus-containing materials at very low temperatures with conspicuous success.¹⁰⁸ Horsfall¹⁰⁹ has described a low temperature storage cabinet designed to accommodate a large number of virus specimens in an easily accessible manner and to maintain them in a state of unaltered infectiousness. The specimen tubes are surrounded by a cold gas mixture resulting from the evaporation of solid carbon dioxide, and a temperature of minus 76 C can be maintained.

COMMON ERRORS IN LABORATORY PROCEDURE

Unquestionably the diagnosis of virus diseases by laboratory methods is subject to numerous difficulties. One frequent error occurs when a latent virus appears during animal passage and is mistaken for that causing the human disease. Several spontaneous infections in apparently healthy mice from various highly inbred laboratory stocks have complicated experimental study of viruses. From apparently healthy mice Traub¹¹⁰ isolated a virus later found to be identical with the lymphocytic choriomeningitis virus isolated by Armstrong and Lilje.¹¹¹ (This virus has been subsequently isolated from a number of animals used in experimental work.¹¹²) Theiler and Gard¹¹³ recovered a mouse encephalomyelitis virus from spontaneously paralyzed stock mice. Olitsky¹¹⁴ was able to recover Theiler's encephalomyelitis virus from the intestinal contents of practically all of his adult stock of white mice. Theiler and Gard¹¹³ recovered the virus in approximately two thirds of 6 month old mice.

The aforementioned viruses can be identified immunologically by the use of specific antisera and by testing surviving immune animals. A virus capable of producing fatal pneumonia in mice was recovered from apparently normal mouse lungs by Dochez and his associates.¹¹⁵ A spontaneous mouse infection against which it is not possible to produce effective antiserum in rabbits and which appears to be similar to that described by Dochez and his co-workers,¹¹⁶ was reported by Gordon, Freeman and Clampitt.¹¹⁶ Freeman¹¹⁷ has pointed out that there may be no immunity to a virus that lies dormant in mice until stimulated by serial passage of lung emulsion or of isotonic solution of sodium chloride inoculated intranasally. More recently Horsfall and Hahn¹¹⁸ recovered a latent virus from normal mice which was capable of producing pneumonia in its natural host and which proved to be different from other viruses which various investigators have found in normal mouse lungs. The strictly pneumotropic virus described by Horsfall and Hahn¹¹⁹ readily immunized mice and produced neutralizing antiserum in rabbits, hence differing from the viruses recovered by the previous investigators.¹¹⁹ A number of reports dealing with the recovery of viruses from other experimental animals have also appeared.¹⁻⁹

Many workers in the fields of biology and medicine believe that if results need statistical evaluation they are of such an inconclusive nature that they should not be considered valid. On the other hand, we are of the opinion that results which look significant may well be given the test of statistical analysis, since occasionally they may not prove to be as conclusive as they appear. Mainland¹⁻¹ discusses the use of statistical methods in such situations. Furthermore in the primary isolation of a virus it is desirable to use a large number of animals. This obviously increases the possibility of getting positive results, and if all animals show signs of infection activation of a latent virus is less likely to have occurred. Also in serum protection tests the use of enough animals makes the conclusions less open to criticism. Schaeffer and Muckenfuss¹²² have shown how difficulty in using large numbers of monkeys in experimental poliomyelitis has often made results invalid.

Authorities differ as to the amount of incubation of serum-virus mixtures necessary in the performance of neutralization tests. Although some workers advocate definite incubation periods, good results have been obtained when only sufficient time to make necessary manipulations was allowed. Incubation may cause some inactivation of the virus, so that it is important that control animals inoculated with normal serum-virus mixtures are carefully observed. It is desirable to inoculate the immune serum-virus mixtures first so that any protection observed cannot be attributed to standing during inoculation of control animals.

The diluent used for suspending the virus-containing tissue is an important factor and is almost always stated. In general, 1 to 10 per cent solutions of normal horse or rabbit serum in saline solution are satisfactory, but it must be made certain that the serum does not contain specific antibodies against the virus used. Infusion broth is also valuable but in 1 instance has been found to be inferior to serum.¹⁻³ Beet infusion broth containing 20 per cent horse serum has been found satisfactory in studies with influenza virus.

Although specific complement fixing antibodies have been demonstrated in many virus diseases, these reactions are so delicate that the execution of the tests, their adequate control and the interpretation of results

demand the utmost care and attention. One of the chief obstacles remains that of nonspecific complement fixation caused by tissue proteins from which viruses are inseparable. For example, the appearance of cer-

body is obtained must be considered. Fairbrother and Hoyle¹²¹ found from their control experiments that the complement fixation which occurred between anti-influenzal ferret serum and influenzal mouse lung was

* This table is intended to serve as a guide to reliable literature for details of technique. The numbers indicated refer to the bibliography which appears on the following page. Only procedures that are considered established are included.

** Refers to the so-called virus pneumonias, although a virus has usually not been recovered.

*** The only known cases are those which have occurred as laboratory infections.

† Not feasible under ordinary circumstances.

†† Complement fixing antibodies are present before neutralizing antibodies make their appearance.

††† Western type.

Because of the high incidence of accidental infections only experienced workers should carry out animal inoculations.

In addition to microscope examination for Negri bodies it is desirable to inoculate suspected brain tissue into mice.

There are some indications that this disease is the same as louping ill (Casals and Webster Science 97 246, 1943).

† The value of the neutralization test is controversial; hence this test is of doubtful significance in poliomyelitis.

† Immunologic in vitro tests using known serum and vesicle fluid or crusts may also be used.

†† Neutralizing antibodies usually appear earlier than complement fixing antibodies.

††† Neutralizing antibodies appear slowly after recovery.

|| Causative agent not known but thought to be a virus.

° Because of insufficient data the laboratory procedure of choice is not as yet established.

§ Disease recently encountered by Smithburn and his associates⁸¹ in Bwamba County, Western Province of the Uganda Protectorate.

§§ A disease recently encountered by Smithburn and his associates⁸² in the West Nile District, Northern Province of the Uganda Protectorate.

§§§ Direct inoculation of chorioallantoic membrane of developing chick embryo with fluid from herpetic lesions is a useful procedure.

tain immunologic effects, such as the Forssman phenomenon, may interfere with interpretation of the results of serologic reactions. The animal species from which antigen is derived and animal species from which anti-

nonspecific in character, as the same effect was obtained with normal mouse lung as antigen. Therefore suitable antigen and serum controls must be included before the results of these tests can be interpreted. Also un-

the same pooled complement is used throughout a series of tests comparisons cannot be made, since the variability of different specimens of complement may vary considerably.

promising but are beginning to displace those in present use. Hirst¹⁻⁶ recently discovered that the allantoic fluid of chick embryos infected with either influenza A or B virus was capable of agglutinating red blood cells.

NEWER PROCEDURES

The accompanying table is designed to include only procedures which in our opinion are fully established and confirmed. Some new methods not only appear very

This phenomenon was utilized by this investigator to detect influenza virus in throat washings and to measure influenzal antibodies in serum. The practicability of this simple in vitro test was pointed out in a later

study.¹²⁷ The same phenomenon was observed independently by McClelland and Hare,¹²⁸ who confirmed the observations of Hirst. Nagler¹²⁹ has described a similar phenomenon with vaccinia virus.

Another *in vitro* test, referred to as the "bacterial agglutination" (B A) technique, was recently described by Roberts and Jones.¹³⁰ This test, which consists essentially in coating the cells of a suspension of bacteria with virus and observing the agglutination of such cells on the addition of the homologous immune serum, was used successfully in studies with St. Louis encephalitis and poliomyelitis viruses. Roberts and Jones observed that the bacteria exhibited greater suspension stability than the collodion particles used in the agglutination test previously described by Cannon and Marshall.¹³¹

Recently Goodner¹³² developed a new *in vitro* technique called "collodion fixation" which permits detection of small amounts of virus or antibody. No literature on the application of this method has appeared.

Experiments are now in progress in the virus laboratory of the St. Louis Health Division to determine the practicability of these newer procedures.¹³³ A discussion of the hazards and difficulties likely to be encountered in the laboratory diagnosis of virus diseases will be published elsewhere.¹³⁴

VIRUS PNEUMONIA

In recent years an increasing number of cases of acute infection of the respiratory tract associated with atypical pulmonary lesions have been reported. These infections have been variously described as acute influenza pneumonia, pneumonitis, acute interstitial pneumonitis, atypical pneumonia, atypical bronchopneumonia of unknown etiology and most frequently "virus pneumonia." In spite of the meager positive results of laboratory studies, the latter name is now quite generally used both by the practitioner in verbal discussions and in many written reports. The diagnosis "primary atypical pneumonia, etiology unknown," recently suggested in an official statement¹³⁵ to the Surgeon General of the Army, appears to be the most suitable designation for this fairly well defined clinical syndrome and implies that an effort has been made to rule out the known bacterial as well as nonbacterial etiologic agents. The nonbacterial agents refer particularly to the viruses of influenza, psittacosis and Q fever. Although a number of attempts¹³⁶ have been made to isolate the causative agent, the etiology of primary atypical pneumonia is by no means established at the present time¹³⁷ and hence no specific laboratory test is now available.

Municipal Courts Building

The Limit of Acclimatization for Man—It is estimated that there are 10,000,000 inhabitants of this globe living at altitudes of 10,000 feet or more. In the mining camps of South America men live at 17,000 feet and work at 18,000 feet. There are monasteries in Tibet where the monks spend their lives at 17,000 feet. It is interesting to note that the miners in South America prefer to live at 17,000 feet and to walk up the additional 1,000 feet to work each day, rather than to live at 18,000 feet. Although an attempt was made to live at 18,000 feet it was abandoned, and these men moved down to 17,000 feet. This indicates that the limit for acclimatization for man is between 17,000 and 18,000 feet—Gemmell, Chalmers L. *Physiology in Aviation*, Springfield, Ill., Charles C. Thomas, Publisher, 1943.

PERIPHERAL NERVE INJURIES DETERMINED BY THE ELECTRICAL SKIN RESISTANCE METHOD

I. ULNAR NERVE

CURT P. RICHTER, PH.D.

AND

DAVID T. KATZ, M.S.

BALTIMORE

In previous papers a method was described by means of which areas of high and low electrical skin resistance can be quickly and accurately defined on all parts of the body.¹ This method was first applied to the delineation of areas of skin denervated by sympathectomy. These areas did not sweat and had a very high electrical resistance. A sharp line, usually less than $\frac{1}{8}$ inch in width, separated the normal areas of low skin resistance from the affected areas of high resistance. Removal of the sympathetic ganglions at any given spinal level produced definite skin resistance patterns which closely conformed to the corresponding sensory dermatomes. This method made it possible to determine exactly the area affected by sympathectomy and the presence of regeneration of the sympathetic nerves.

In a later study with this method, well circumscribed areas of low electrical skin resistance were found in normal individuals at room temperature on the face, hands and feet and in the axillas and antecubital fossae. On the face the area had an oval shape and included the eyes, nose and mouth, on the hands it included the palmar surface and the distal parts of the dorsal surfaces of the fingers, on the feet it included the plantar surface and a marginal band of about 1 inch along the sides. In warm external temperatures and with any kind of sympathetic stimulation these areas of low electrical skin resistance on the face, hands and feet became larger, while in the cold and during sleep they became smaller. The possible uses of these areas for the objective study of peripheral circulatory and other disturbances have been discussed in our previous papers.

This method is now being used (1) to define cutaneous areas innervated by the peripheral nerves, (2) to define areas affected by trauma or sectioning of the peripheral nerves and (3) to determine the effects produced by nerve suture and spontaneous regeneration. The present paper deals only with observations made on the ulnar nerve. In the first part of this study we mapped the areas of skin which are affected by a temporary palsy of the ulnar nerve produced by an injection of procaine hydrochloride into the nerve at the elbow. In the second part we mapped the areas denervated by total or partial accidental sectioning of the nerve at various levels of the arm. In some instances the observations were made immediately after the nerve was sectioned and in others not until several months or even years later. So far we have not had sufficient

David T. Katz is Henry Strong Denison Scholar, 1943-1944. From the Psychobiological Laboratory, Phipps Psychiatric Clinic, Johns Hopkins Hospital. This investigation was carried on under a grant from the John A. Mary R. Markle Foundation. 1. Richter, C. P., and Woodruff, B. G. Changes Produced by Sympathectomy in the Electrical Resistance of the Skin. *Surgery* 10: 937, 1941. 2. Facial Patterns of Electrical Skin Resistance. *Bull. Johns Hopkins Hosp.* 70: 442-459, 1942. Whelan and Richter.²

time to follow the entire process of regeneration of the ulnar nerve from the time of suturing to full recovery. In all instances simultaneous observations were made on sensory changes accompanying nerve section and suture.

METHOD

For most of the following observations we used a small dermatometer which was specially designed for this purpose. It consisted of a small portable box which contained an ammeter, two variable resistances, a 4.5 volt battery and two lead wires and electrodes. One electrode made of a small zinc disk soldered to a wire clip was securely fastened to the lobe of one ear. This electrode remained fixed throughout the examination. A paste made of kaolin and saturated zinc sulfate solution established contact between the electrode and the ear and a prick to the skin eliminated the resistance of the skin beneath this electrode. The movable electrode a small zinc disk 1 cm in diameter was soldered at right angles to the end of an insulated 3 inch copper rod. By holding the rod in the hand the operator could bring the flat surface of the disk into contact with the skin on any part of the body.

At the outset of an examination, the movable electrode was pressed lightly against the skin within an area suspected of having been denervated by peripheral nerve injury. By means of the variable resistance in the instrument the current flowing through the completed circuit was adjusted so that an ammeter deflection of only a few scale divisions was obtained. Then while maintaining a close watch on the ammeter the movable electrode was moved over the surface of the skin until an area of low skin resistance was reached as indicated by a sharp deflection of the pointer across the ammeter scale. The electrode was then moved back and forth between areas of high and low resistance until the exact point of change was located. The change from low to high resistance usually occurred within a distance of $\frac{1}{8}$ inch or less. By repeating this procedure in adjoining areas other points of sharp resistance change were determined and marked with a skin pencil. This process was continued until the entire area of high resistance was delineated. The points so obtained were then joined together. Areas were recorded on charts and in most instances the hands photographed.

In a warm external environment the resistance of the skin on normal parts of the body is usually very low as compared with that present on denervated areas. Under such conditions mapping tests can be made at once without further preparations. During the cold months of the year or at any other times when the patient is cold, the skin resistance on the normal areas may be as high as on the affected areas. It is necessary then either to heat the patient for a few minutes in a hot air cabinet or under a heat cradle or to give a subcutaneous injection of pilocarpine ($\frac{1}{10}$ gram [0.0065 Gm]) or to give acetylsalicylic acid and hot water or tea. Such procedures reduce the resistance of the normal skin but have little or no effect on the high resistance of the denervated areas, thereby bringing out a sharp line of demarcation between them.

Heating the body also eliminates the normal hand pattern, which otherwise in some instances may be mistaken for parts of the pattern produced by the peripheral nerve injuries.

In many instances the skin resistance patterns were checked with the Minor starch-iodine sweating test. This test however, does not usually give good patterns on the hand, particularly on the palmar surface.

On most persons simple sensory tests were made for pain and touch, the pin prick and cotton swab being used.

RESULTS

Patterns of High Electrical Skin Resistance Produced by Injections of Procaine Hydrochloride In and Around the Ulnar Nerve at the Elbow

In these studies 4 to 5 cc of a 1 per cent solution of procaine hydrochloride was infiltrated in and around the ulnar nerve at the elbow. Skin resistance and sensory tests were made every few minutes to determine the first appearance and the duration of the appearance of the areas of high electrical skin resistance and of the areas of anesthesia.

Usually within five minutes patterns of high skin resistance and anesthesia could be detected. For the

FIG. 1.—Ulnar nerve patterns of high electrical skin resistance following procaine injection of the ulnar nerve at the elbow.

first few minutes the outlines of the patterns were not sharply defined; later they became as sharp as those which bound sympathectomized areas. The areas of skin resistance and of anesthesia agreed very closely. They both disappeared after the lapse of thirty to forty-five minutes. Figure 1 shows the patterns that were found in 6 normal persons. The pattern showed some individual variations, but in general they agreed closely with the ulnar patterns which have been determined by other methods.

Skin Patterns of High Resistance Found in Patients with Total or Partial Section of the Ulnar Nerve³

CASE 1.—N. B., a white man aged 42, sustained a laceration of the ventral and ulnar aspects of the wrist on May 21, 1942. In the course of the injury, which was caused by broken window glass, the ulnar nerve was cleanly divided and the ulnar artery cut. On the same day the nerve was sutured. One month later when the patient was sent to us for examination the ulnar patterns of high electrical resistance shown in figure 2 (N. B.) were clearly defined on his hand. These patterns were almost the same as some of those shown in figure 1, which were found after injection of procaine hydrochloride.

³ These patients were referred to us by Lieut. Col. R. Glenwood Spurling of the Walter Reed General Hospital in Washington, D. C., by Dr. James G. Arnold, Jr., of the University Hospital of the University of Maryland, and by Drs. Herbert E. Sloan, Jr. and Marcus M. Ravitch of the Johns Hopkins Hospital.

² Whelan, F. G., and Richter, C. P., Electrical Skin Resistance: Technique Used to Map Areas of Skin Affected by Sympathectomy and by Other Surgical or Functional Factors. *Arch. Neurol. & Psychiat.* 49: 44 (March) 1943.

in and around the ulnar nerve at the elbow. Here again the areas of high electrical skin resistance corresponded almost exactly with the areas of anesthesia.

CASE 2—J W, a Negro aged 51, in May 1942 suffered a compound fracture of the left shoulder. An open reduction was performed. Ulnar palsy was noticed when the cast was removed. The patient was examined by us on October 10. At that time it was noticed that he had contractures of the long tendons of the fourth and fifth fingers, atrophy of the intrinsic hand muscles (except those supplied by the median nerve) and a complete loss of sensation over the ulnar field. It was found that he had a fairly typical ulnar pattern of high electrical skin resistance (fig 2, J W). Clearly the nerve must have still been severed at this time. A skin mapping test made at the time of the fracture would have revealed at once the severance of the ulnar nerve.

CASE 3—F S, a Negro aged 45 sustained a stab wound in the right arm in the ulnar region just above the elbow. When he was brought to the hospital he had a complete palsy of the lower arm attributed to a tourniquet which had been in position on the upper arm for more than seven hours. According to the examinations made at that time no nerve had been cut. Seven days later, dorsiflexion of the fingers and sensation began to return. Three weeks later the patient could pronate his forearm slightly but was unable to supinate it. Intrinsic muscles of the hand were almost completely paralyzed.

Fig. 2—Ulnar nerve patterns of high electrical skin resistance following partial and total section of the ulnar nerve.

and flexion and extension of the wrist were almost entirely gone. Three months later the patient was sent to us for examination. Figure 2 (F S) shows the typical ulnar pattern of high electrical skin resistance that was found on the patient's hand at this time. It corresponded closely with the area of anesthesia. The ulnar nerve must have been either severely injured or actually severed by the stab wound. A skin resistance mapping test made at the time of the original surgical examination would have demonstrated the serious condition of the ulnar nerve.

CASE 4—E L, a white man aged 41, on Sept 1, 1942 suffered a blow on the medial side of the upper third of the humerus, with a resultant ulnar palsy. Electrical skin resistance examination was made on December 29. A typical area of high resistance was found over the ulnar field. The high resistance also extended above the medial side of the arm including the medial antibrachial cutaneous nerve and possibly the medial brachial cutaneous nerve up to the site of injury.

CASE 5—K F, a white man aged 26, on Feb 19, 1942 received a bomb fragment in the medial side of the lower third of the humerus. There was a complete ulnar nerve palsy. On September 4 a neuroma was excised and a transposition and end to end anastomosis were performed. An electrical skin resistance test was performed on December 30. An area of high resistance (about 5,000,000 ohms) was found over the hypothenar eminence and over a narrow band on the ulnar side of the dorsum of the hand, the fifth digit and two small

spots on the fourth digit. The remainder of the hand had a lower resistance (under 500,000 ohms). The area delineated corresponded well with the area of complete pain and touch anesthesia. This pattern is not as extensive as the typical ulnar field and therefore would indicate partial recovery.

CASE 6—M H, a white woman aged 21, accidentally cut her right wrist on a sharp edged vessel on Aug 25, 1942. The wound was 8 cm in length and was located on the ventral and lateral surfaces of the wrist 2 to 3 cm above the hypothenar eminence. The ulnar nerve and artery and the long flexor tendons on the ulnar side of the wrist were cut. The nerve and tendons were sutured. When examined by us three months later, her hand showed a definitely constricted ulnar pattern. Figure 2 (M H) shows that the area of very high resistance included only the little finger and a narrow band along the edge of the hand on both the palmar and the dorsal surface. Areas of intermediately high resistance (light stipple) were found (1) on the inner surface of the fourth finger (2) between the scar and the area of very high resistance and (3) on the dorsum which filled in most of the original ulnar pattern. (The high resistance area at this time was 3,600,000 ohms while the area of low resistance was from 140,000 to 150,000 ohms.) These areas of very high and intermediately high resistance corresponded closely with areas of total and partial anesthesia respectively. It is clear that suture of the ulnar nerve had been successful and that part of the nerve had already regenerated.

CASE 7—D D, a white man aged 42, fractured his humerus and dislocated his shoulder on April 22, 1942. The shoulder was set at once and placed in a cast. Five weeks later when the cast was removed it was found that the patient had a complete nerve palsy. Five months later when he was examined by us his hand showed only a very small ulnar pattern, as may be seen in figure 2 (D D). On the dorsal surface the area of very high resistance included only the tip of the little finger and on the palmar surface the little finger and a narrow strip along the edge of the hand. It therefore appears that in the beginning the ulnar nerve must have been either partially or completely cut and in the meanwhile must have become at least partially regenerated.

CASE 8—J E, a white man aged 41, in July 1935 sustained a 3 cm laceration on the ulnar side of the left wrist on the volar surface extending around to the dorsal surface. The ulnar nerve was cut at this point. He was first seen at the Johns Hopkins Hospital in February 1936. At this time he had a healed laceration with atrophy of the intrinsic hand muscles and a complete ulnar palsy and loss of sensation over the ulnar field. A nerve suture was performed. One year later he noticed returning sensitivity and could distinguish heat and cold but still had complete loss of tactile sensation. The muscles were atrophied and very weak. When examined by us in October 1942, six years after the nerve suture, his hand showed a small area of intermediately high resistance on the inner surface of the fifth digit and on the dorsal surface of the tip of the fifth digit. However, he still had an area of partial anesthesia over the entire ulnar field, as may be seen in figure 2 (J E). Thus the ulnar nerve had not completely regenerated over a period of six years. The sympathetic functions had apparently completely recovered long before the sensory functions returned to normal.

CASE 9—R S, a white man aged 36, sustained a laceration of the left arm and forearm on Aug 17, 1939 in an automobile accident. He had a large U shaped wound on the ulnar side of the forearm about 4 cm below the medial epicondyle. Distal to this there was another wound. When the patient first came to the Johns Hopkins Hospital in December 1939 he had a typical ulnar nerve palsy with muscular atrophy, contracture and hypesthesia. When examined by us three years later the hand showed a very small area of intermediately high

resistance on the inner distal surface of the fifth digit and over the dorsal surface of the tip. The remainder of the ulnar field showed low resistance indicating recovery. The entire ulnar field showed hyperesthesia. Here again there is seen a decided discrepancy between the rate of sympathetic and the rate of sensory recovery.

CASE 10—A H, a white man aged 48 injured his ulnar nerve at the elbow in an automobile accident in 1907. He was operated on for a fractured humerus but apparently the ulnar nerve was not sutured. When examined by us in December 1942 his hand showed no skin resistance patterns whatever. There was a well defined ulnar palsy with muscular atrophy and contractures and hyperesthesia. In this case the sympathetics had entirely regenerated while the muscle and sensory functions had only partially recovered.

COMMENT

The results of these observations show that in the electrical skin resistance mapping test we have a simple accurate and practical method of defining areas affected by peripheral nerve injuries. One of its chief advantages is that its successful use does not depend in any way on the cooperation of the patient. Even in conscious intelligent patients it is often difficult and time consuming to map areas of anesthesia while in disoriented patients shocked by civilian or wartime accidents mapping of areas of anesthesia becomes almost impossible. In cases of suspected malingering the electrical skin resistance method supplies a more reliable test than the subjective report. In cases of severe fractures and the like in which nerves may become traumatized or sectioned the skin resistance mapping test should make it possible to determine at once the site and extent of nerve involvement. As will be shown in later papers and as was pointed out in the present paper, this method should help to determine the success of nerve sutures and to follow the progress of regeneration. With the combination of the accurate means of defining the nature of the lesion as well as the degree of functional injury as indicated by the actual absolute skin resistance readings in ohms, it should become possible to determine which procedures speed up regeneration and which ones retard it. It should also be possible with this method to work out in more detail the interrelationship between the rate and character of regeneration of the autonomic and sensory nervous systems. The nature of sensory and sympathetic "overlap" which might occur as a result of diffusion from contiguous nerve fields is under investigation.

SUMMARY

1 By means of the electrical skin resistance mapping test and procaine injections of the ulnar nerve at the elbow, the ulnar field of sympathetic innervation was defined in 6 normal persons.

2 By means of this test the affected areas of skin were sharply delineated on 10 patients with ulnar lesions of recent and long standing produced by accidental cuts intentional stabs compression from fractures or by bomb and shell fragments.

3 The simplicity, accuracy and speed of the method make it useful for the exact examination of all types of peripheral nerve lesions for the determination of the effects of nerve sutures and different kinds of treatment.

SUCCINYLSULFATHIAZOLE IN THE TREATMENT OF BACILLARY DYSENTERY

CAPTAIN THOMAS L. ROBERTS

AND

LIEUTENANT COLONEL WORTH B. DANIELS

MEDICAL CORPS, ARMY OF THE UNITED STATES

The history of dysentery runs parallel with the history of wars. Through the centuries it has been the scourge of armies. Its morbidity has decided campaigns. It almost defeated the British at Gallipoli in 1915 when it was responsible for a high proportion of the 120,000 casualties from sickness in that area. Whenever troops are encamped in the field, even in training areas this disease is apt to occur unless there is constant and unremitting attention to field sanitation.

During a six weeks period in the late summer of 1942 an epidemic of dysentery occurred in a large military organization encamped in the field in North Carolina. The epidemiology and source of this outbreak were studied by Sands and Riley.¹ The bacteriology of the epidemic has been investigated by Kuhns² and his co-workers. The bacteriologic studies of the hospital cases were made by Brown and Pohle.³ It was clearly shown that the epidemic was fly borne and due to *Shigella paradysenteriae* Boyd-88.

The present paper concerns itself with the clinical aspects and treatment of the hospitalized patients. Two hundred and fifty-two soldiers from the organization concerned were admitted with dysentery during this period. Two hundred and twenty-five of the cases are used as the basis of this analysis.

CLINICAL PICTURE

The onset in the majority of cases was sudden with chills, fever, headache, backache, malaise, nausea, vomiting, cramping abdominal pain, tenesmus and diarrhea. In many instances the diarrhea became rapidly worse, and some soldiers stated that they had had fifty stools in the twenty-four hours prior to admission. The maximum number of stools observed in the hospital was fifteen in twenty-four hours and the average seven. The stools were watery, were greenish or yellowish brown and frequently contained mucus. They were bloody in 18 per cent of the cases. Colicky abdominal pain was common (81 per cent) and often severe enough to make the men double up and groan with pain. Tenesmus was not severe and was present in only 21 per cent of the cases. Generalized abdominal tenderness of moderate degree was usual. Hyperperistalsis was fairly frequent but distention occurred only occasionally. Fever was present in the majority (69 per cent). The highest temperature was 104.8 F and the average maximal temperature was 100.8 F. Shaking chills were present only at onset, but chilliness during the febrile period was frequent (42 per cent). Weakness, listlessness and anorexia were common and were

directly proportional to the height of the fever and the severity of the diarrhea. Early in the illness, prostration from fever and loss of fluids was great enough in some cases to require the parenteral administration of fluids. Fever persisted, as a rule, for from two to three days, and diarrhea usually disappeared after four days of treatment. The great majority of patients had less residual weakness than would be expected following an acute febrile illness with severe diarrhea. There were no complications and no deaths. Tables 1, 2 and 3 indicate the frequency and duration of some of the manifestations.

During the early period of the outbreak all patients were treated symptomatically with bed rest, a bland low residue diet and camphorated tincture of opium 8 cc after each bowel movement until the diarrhea had decreased. In the cases of more severe involvement morphine was necessary.

At first, stool cultures were made from fresh specimens sent to the laboratory. However, early in the outbreak the rectal swab method advocated by Cruickshank and Swyer⁴ was adopted with excellent results. This method is quick, is easily carried out and yields a much higher incidence of positive results than the usual method of stool collection.

TABLE 1—Incidence of Signs and Symptoms

	Controls (116 Cases), per Cent	Succinyl sulfathiazole (89 Cases), per Cent	Average (225 Cases) per Cent
Diarrhea	88.9	84.2	86.4
Cranpinh	75.0	88.7	81.8
Fever	66.9	71.9	69.1
Chills	11.8	39.1	42.0
General malaise	11.1	37.0	40.0
Headache	36.0	12.5	34.2
Nausea and vomiting	33.5	33.0	33.4
Leucocytosis	17.2	30.3	21.6
Delirium	1.4	1.1	1.2
Tenderness	8.8	32.8	34.1
Hyperperistalsis	18.1	22.4	20.1
Distention	9.5	0.8	5.1

In the majority of instances cultures were made in selenite F broth and on Shigella-Salmonella agar (Difco) plates. These cultures were transferred to Kleigle's iron agar slants. Further differentiation of the organism was made by sugar fermentation and by agglutinations. *Shigella paradysenteriae* Boyd-88 was isolated from 36 per cent of the patients on admission, and this figure was increased somewhat by subsequent cultures. The leukocyte count during the acute phase of the illness ranged from 3,300 to 17,000 per cubic millimeter of blood. The majority of the patients had normal leukocyte counts. Leukopenia, however, was common (21.4 per cent). In this group the average ratio of polymorphonuclear leukocytes to lymphocytes was 55.5 to 41.2.

Succinylsulfathiazole (2-[*p*-succinyl aminobenzene-sulfonamide] thiazole), recently synthesized by Moore and Miller,⁵ was used in the treatment of half of the later cases. All the early cases were treated purely symptomatically. Poth and Knotts⁶ have reported the use of this compound in more than 100 cases presenting various intestinal lesions and acute intestinal infections. The oral administration of the drug exerts a decided bacteriostatic action in the bowel and can reduce the

coliform organism from 100 million to 1 thousand per gram of wet feces in three to seven days. The usual dosage is 0.25 Gm per kilogram of body weight as an initial dose, followed by 0.25 Gm per kilogram daily divided into six equal doses. In our cases this dosage schedule was continued until the patient's temperature had been normal for two days and until diarrhea had

TABLE 2—Fever

	Controls	Succinyl sulfathiazole Treated Patients

Average days' duration of fever	2.8	2.1

been absent for an equal period. It is essential to give an adequate dosage of opiates to check the diarrhea so that the drug will not pass through the bowel too rapidly. The compound is sparingly soluble in water and poorly absorbed from the intestinal tract so that its action is essentially in the bowel. The total urinary excretion is less than 5 per cent.⁷ The blood level of succinylsulfathiazole was determined in a few of our cases. It was always less than 1 mg per hundred cubic centimeters of blood. Since the bacteriostatic action of the sulfonamide compounds is due to the presence of the free amino radical on the benzene ring, it is probable that the mode of action of this drug is by its hydrolysis to succinic acid and free sulfathiazole in the intestinal tract.⁸ The concentration of sulfathiazole so derived is from 50 to 200 mg per hundred cubic centimeters of feces. These concentrations have been shown to be both bacteriostatic and bactericidal. The succinyl radical presumably inhibits the absorption of the drug from the upper intestinal tract.⁸ After slow hydrolysis the active portion, sulfathiazole, is freed and reaches a high concentration in the large bowel. Under the influence of this drug the stools become "semifluid, small in bulk, somewhat gelatinous in appearance and relatively odorless." The only reactions are a mild perianal irritation and a tendency to slight diarrhea.⁷ Kirby and Rantz⁸ used this drug in the treatment of 5 dysentery carriers. The dysentery bacilli disappeared from the stools of all 5 carriers within one week of treatment and remained absent during the follow-up period of thirty to sixty days.

Average days' duration of diarrhea	4	4

PLAN OF STUDY

When the clinical diagnosis of bacillary dysentery was made, immediate rectal swab cultures were taken. Each patient admitted was given a number, and those with even numbers were treated symptomatically, as previously outlined. Those with odd numbers were given the same treatment but succinylsulfathiazole was also used. Tables 1, 2 and 3 indicate that the treated and control groups were entirely comparable. Eighty-

nine patients were treated with succinylsulfathiazole and 130 patients were used as controls. Follow-up cultures in the two groups covered a period of from one to three weeks with an average of eighteen days. Further cultures could not be made because this organization was ordered to another locality. All follow-up cultures were taken by the rectal swab method after sufficient time had elapsed for the drug to be eliminated from the bowel. Para-aminobenzoic acid was added to all culture mediums.

ANALYSIS OF RESULTS

The average duration of fever in the treated group was slightly less than in the controls, that is 22 as compared with 28 days. There was no significant difference in the daily number of stools or the duration of the diarrhea in the two groups. It was felt that the patients in the control group were on the whole more comfortable than those treated with succinylsulfathiazole. It was obvious that the drug produced no amelioration of symptoms nor did it shorten the course of the illness in this outbreak. There was no evidence of drug toxicity in any of the treated cases.

In the control group of patients, 44 (32 per cent) had positive cultures on admission and 8 (18 per cent) of these had positive follow-up cultures after recovery.

TABLE 4—Results of Treatment

	Number	Results of Cultures		Percentage of Positive Follow-Up Cultures	
		Admission	Follow-Up	Whole Group	Bacteriologically Positive Cases
Controls	126	44 positive 92 negative	8 positive 7 positive	11.0	18.2
Succinyl sulfathiazole	89	25 positive 64 negative	1 positive 0 positive	1.1	2.6

* This patient's culture was negative for three weeks. He was discharged from the hospital and was in the field (where original disease contracted) for ten days before a positive culture was obtained. The probability of reinfection must be considered.

Of the 92 control patients who had negative cultures on admission, 7 (7 per cent) had positive follow-up cultures. Fifteen patients (11 per cent) of the entire untreated group had one or more positive follow-up cultures. Of the 89 treated patients, 38 (43 per cent) had positive cultures on admission. The higher incidence of positive cultures in the treated group is probably the result of the rectal swab method of culturing which was begun at about the time the decision was arrived at to use succinylsulfathiazole in treatment. Some of the patients reported as controls were admitted to the hospital prior to the use of succinylsulfathiazole in treatment when the rectal swab culture method had not been adopted. Only 1 (2.6 per cent) of these 38 patients had a positive follow-up culture and none of those originally negative later showed a positive culture. Of the entire group of 89 treated patients the incidence of positive follow-up cultures was 1.1 per cent. This is in striking contrast to 11 per cent in the untreated group. If the cases which were bacteriologically positive on admission are considered alone, the ratio of positive follow-up cultures is 18.2 per cent in the untreated group as compared to 2.6 per cent in the treated.

CONCLUSIONS

1 Two hundred and twenty-five soldiers ill with dysentery due to *Shigella paradyseriae* Boyd-88 have been studied.

2 Succinylsulfathiazole produced no amelioration of the illness nor did it shorten its duration. This would be expected in an illness of only four days' duration.

3 The carrier rate in the bacteriologically proved cases when succinylsulfathiazole was given, was 2.6 per cent and in a comparable untreated group 18.2 per cent.

SPECIFIC TREATMENT OF TYPHOID

THE INEFFECTIVENESS OF SULFATHIAZOLE AND IMMUNE SERUM

MAJOR ROBERT J. HOAGLAND

MEDICAL CORPS, ARMY OF THE UNITED STATES

Between Feb 25 and March 21, 1942, 59 patients with typhoid were admitted to Provisional Hospital No 3 in the Territory of Hawaii. All of the patients except 2 were children between the ages of 12 and 16, and all except 2 attended or were employed at the Washington Junior High School. Investigation by the public health authorities disclosed that a healthy intestinal typhoid carrier, employed as a food handler in the school, produced the epidemic by contaminating food eaten by the pupils at one meal. The clinical aspects of this epidemic were described by Hoagland and Fleming¹.

All the patients were hospitalized in the same institution and all were under my control. All except 2 were in a similar state of nutrition, and all except 2 were infected by the same strain of *Eberthella typhosa*. The variables of age, nutrition, climate and strain of infecting organism were absent. In addition, four fifths of the patients entered the hospital in approximately the same stage of the illness (between the fifth and fourteenth days).

When this epidemic occurred there were no reports in the literature concerning the use of sulfathiazole in the treatment of typhoid. It was therefore decided to give sulfathiazole to some of the patients and to withhold the drug from a control group.

Sulfanilamide was stated to be of value in a series of 7 cases.² All were treated with azosulfamide and sulfapyridine, there were no controls. In 3 cases the drug was given at a time when spontaneous improvement might have been expected (on the twenty-eighth day in 1 case and between the thirty-sixth and fifty-seventh days and the eighteenth and twenty-fifth days in other cases). As a rule the drug was given over a period of five to ten days before improvement was manifest, hence it is questionable whether improvement was the result of the administration of the drug or was only concomitant with it. One of the patients received an antityphoid serum as well.

The use of sulfaguanidine in the treatment of typhoid was reported by Watt and Peterson.³ Six patients were treated with 20 Gm of sulfaguanidine daily for eight to ten days. No untreated patients were used as controls. The authors concluded that the drug had no effect on the course of the disease or on the disappearance of *E. typhosa* from the patients' feces.

Hall⁴ used sulfaguandine to treat 5 patients with typhoid. Controls were not used. An initial dose of 0.1 Gm. of the drug per kilogram was followed by 0.05 Gm. per kilogram every four hours for one week. He believed that although the small number of cases precluded the drawing of definite conclusions his results

indicated that sulfaguandine was ineffectual in the treatment of typhoid-paratyphoid infections.

There are many reports concerning the use of serum obtained from horses previously inoculated with *E. typhosa*. It would be unprofitable to attempt to review all of them. The few reports available to me were analyzed.

Horse antiserum was used in the treatment of 73 patients during a milk borne epidemic of typhoid.⁵ Twenty were treated during the first two weeks of their illness, 13 during the third week and 40 after the third week. There were no controls. The criterion of a favorable effect was the lowering of the temperature within forty-eight hours after administration of the serum. The temperature did not necessarily have to return to normal but had to remain lower than before the injection for at least seven days. The mortality rate was 9.5 per cent. The authors believed that beneficial effects of serum might be delayed seven days. A study of the temperature curves of the cases reported by Hoagland and Fleming¹ reveals that spontaneous recovery in typhoid is likely to take place within less than seven days from any given date after the second week; hence 53 of these patients might have been expected to have a spontaneous recovery at any time within a week after their admission to the hospital.

The use of horse serum was also reported by Robertson and Yu⁶ and by Felix.⁷ The former mentioned no controls and treated many of their patients in the

third week of illness. The latter stated that fever was clearly shortened and suppressed in 23 cases but was uninfluenced in 20 cases and that patients might show a lessening of toxemia without an accompanying effect on pyrexia.

PRESENT STUDY

Sulfathiazole was given to 20 patients. Nineteen, weighing between 80 and 110 pounds (36 and 45 Kg.), received 4 Gm. of sulfathiazole daily for five days. One adult received 6 Gm. daily for five days.

Five patients were given injections of 150 cc. of pooled human serum obtained from previously inoculated persons. The donors of the serum had had an average of three series of inoculations (of three injections each) of typhoid vaccine. They had all received their last series of injections between two and five months prior to the withdrawal of serum.

"The typhoid protective titer of the pooled serum was between 100 and 1,000 minimum lethal doses, that is, 0.1 cc. amounts of serum protected all mice that were subsequently inoculated with 100 m. l. d. of a virulent typhoid culture, while 50 per cent of the animals, receiving the same amounts of serum, survived the inoculation of 1,000 m. l. d. of the test organism." This degree of protection is "fair."⁸

Nine patients were treated with sulfaguandine by private physicians before they entered this hospital. The doses used varied and in my opinion, were deficient in most instances. One patient received this drug after admission. Although the administration of this drug was not under my control and its use in inadequate doses did not constitute a fair trial, it may be of some interest to include these cases in the presentation of results without drawing any conclusion.

Thirty-seven patients selected entirely at random were treated only symptomatically. These controls were chosen only because they happened to be in certain rooms. Three patients received two forms of treatment, as shown in table 3.

RESULTS

Results are presented in the accompanying table, which are self explanatory. No toxic effects attributable to the use of the sulfonamide compounds were observed. The incidence of complications was about the same in treated patients and controls. Since none of the patients became typhoid carriers, the efficacy of medi-

COMMENT

The well known variability of the severity of typhoid makes the use of control cases essential in evaluating the efficacy of any drug used in its treatment. The fact that variables were reduced to a minimum in this study made comparison between controls and treated patients valid.

The most convenient index of the efficacy of treatment was the graphic temperature chart. It was

The cessation of fever usually occurred independently of sulfathiazole therapy. Occasionally treatment and a drop in temperature were concomitant. It, here and there a patient treated with sulfathiazole was studied without regard to untreated patients, one might erroneously infer that the drug had had a favorable effect on the disease. However, when time and time again the fever of control and of treated patients would abate during similar phases of the illness, it became apparent

Given by private physician before patient's entry into the hospital

believed that this standard was not only convenient but thoroughly reliable. It was the unanimous opinion of all physicians and nurses attending these patients that toxicity and fever were directly proportional. Therefore return of the temperature to normal was used as the criterion of recovery. On the other hand it was noted that when patients had febrile relapses they did not appear to be ill. Temperatures became normal as early as the twelfth day and as late as the eighty-first day of illness, either by lists over a period of three to seven days or abruptly within twenty-four hours.

that at a certain time during the course of the disease the fever subsided and the patient felt well whether or not the drug had been used.

The use of sulfaguanidine was not under my control. Furthermore insufficient doses were used. In the few cases in which dosage approached adequacy, no beneficial effects were observed. It would seem illogical to use in a blood stream infection a drug whose effect is largely confined to the intestine.

Early administration of serum in such diseases as diphtheria and pneumonia is considered to be of great importance. Typhoid however is usually not diag-

nosed until the patient has been ill at least five to ten days. Therefore serum could rarely be used early. All patients in my series who received serum were treated on or after the eleventh day of illness. A stimulating dose of vaccine two to three weeks before the donors were bled would have produced a serum of higher titer.⁸ However, the occurrence of a typhoid epidemic is unpredictable, hence previously inoculated donors cannot be reinoculated before its outbreak. The donors used had received many inoculations and had fortuitously received their last series of injections relatively recently.

The dose of serum employed was large, fifteen hundred times the amount that protected all mice inoculated with 100 minimum lethal doses of a virulent typhoid culture and 50 per cent of the mice inoculated with 1,000 minimum lethal doses.

SUMMARY AND CONCLUSIONS

1 Fifty-nine patients with typhoid were hospitalized simultaneously. All except 2 were between 12 and 16 years of age, and all except 2 were infected by the same strain of *Escherichia typhosa*.

2 The administration of sulfathiazole did not affect the course of the illness, complications, mortality rate or occurrence of the carrier state.

3 The use of serum obtained from previously inoculated persons was valueless.

PYURIA OF THE NEWBORN TREATED WITH SULFATHIAZOLE

A REPORT OF THREE CASES ILLUSTRATING DIFFERENT ASPECTS OF THE SYNDROME

ALFRED FLORMAN, M.D.

AND

MURRAY H. BASS, M.D.

NEW YORK

During the neonatal period changes take place very rapidly in the anatomy and physiology of the child. These changes are often reflected in those disease pictures peculiar to this period of life. Examples of such conditions are tetany of the newborn, paroxysmal tachycardia, pyloric stenosis and the condition we are describing in this communication, namely pyuria of the newborn. In all these conditions the change from fetal to extrauterine existence, with the sudden alteration in physiologic processes this entails, may easily account for disturbances in the smooth functioning of the various organs. It is our purpose in this communication to reemphasize this observation and to report 3 cases of pyuria of the newborn treated with sulfathiazole.

The newborn child's urine may contain casts and cellular elements in the absence of disease.¹ These usually clear with the ingestion of large amounts of fluid.² However, there are reports in the literature which suggest that during this period of relative anuria the urinary tract may furnish an especially good focus for infection.³ That physiologic changes peculiar to this period of life modify the disease picture of pyuria is also suggested by the fact that, unlike what is observed

in a slightly older group, pyuria in the newborn is more frequently observed in the male. It is a relatively benign disease and recurrences seem to be infrequent.

Although the disease was first described by Kovalesky and Moro⁴ in 1901, Happ⁵ could find only 37 case reports when he summarized the literature through 1932. The urine of newborn infants is now examined more frequently, so that the diagnosis is being made more often. In 1935 Craig³ reported observation on 61 newborn children, of which 53 showed definite pyuria.

The 3 cases which form the subject of our paper were recognized over a period of seven months in a pediatric service which does not have any direct affiliation with an obstetric hospital. They are being reported because they illustrate so well several different aspects of the syndrome pyuria of the newborn.

CASE 1—*Illness started at 10 days of age with resulting uricemia and difficulty in feeding. Pyuria found to be due to atypical Escherichia coli. The clinical picture was complicated by anemia of fetal erythroblastotic origin. The child was given Rh negative transfusion and sulfathiazole. The urine was clear after two and one-half weeks except for occasional leukocytes and a trace of albumin.*

S. H., a boy, admitted to the Mount Sinai Hospital at 6 weeks of age because of poor feeding and failure to gain weight, had been born at term weighing 6 pounds 5 ounces (2,870 Gm). He was circumcised at 1 week without difficulty. At 10 days of age he developed fever and his eyes were noted to be puffy. When he was 3 weeks old there was an episode of twitching of the arms and legs which responded to calcium. He had several mild attacks of diarrhea. At 6 weeks of age he was hospitalized weighing only 6 pounds (2,728 Gm). He was a poorly nourished child with a mild upper respiratory infection. The temperature was 102 F. There was an icteric tinge to the skin. The liver edge and tip of the spleen were both 2 cm. below the costal margin. The umbilical stump was everted but clean. The penis was that of a normal circumcised male infant. The hemoglobin was 45 per cent, red blood cell count 2,030,000 and white blood cell count 49,600 with 57 per cent polymorphonuclear cells. No nucleated red blood cells were seen. The red cell fragility test was normal. The icterus index was 18 (water) and 12 (acetone). Rh studies showed the mother to be Rh negative and the child Rh positive. The urine observed on admission was cloudy, the specific gravity was 1.010, albumin was 1 plus and the sediment was loaded with pus cells. On culture atypical *Escherichia coli* was recovered. This organism did not ferment lactose but did ferment with acid and gas production maltose, sucrose, glucose and mannite. This same organism was grown from a urine obtained four days later. Blood culture on admission was sterile. Blood chemistry showed evidence of uremia: urea nitrogen 112 mg per hundred cubic centimeters, carbon dioxide 27.4 volumes per cent, calcium 6.9 mg per hundred cubic centimeters and phosphorus 7.5 mg per hundred cubic centimeters, total protein, 8.2 Gm per hundred cubic centimeters. The child was given intravenous fluids, several transfusions of Rh negative blood, sulfadiazine for twenty-four hours and then sulfathiazole. The drug was continued for one month, during which time blood levels of between 5 and 10.1 mg per hundred cubic centimeters and urine levels of 64 to 98 mg per hundred cubic centimeters of free sulfathiazole were attained. After forty-eight hours the patient's temperature fell to normal and twenty-four hours later there were many fewer leukocytes in his urine, though albumin was still present. The urine slowly cleared and after two and one-half weeks, although albumin was still present, only a rare white blood cell was noted. At that time the blood chemistry had changed as follows: the urea nitrogen was 14 mg per hundred cubic centimeters, carbon dioxide 44.2 volumes per cent, calcium 11.1 mg per hundred cubic centimeters and phosphorus 5.7 mg per hundred cubic centimeters.

meters. After six weeks the only abnormal finding in the urine was a faint trace of albumin. The jaundice observed on admission disappeared in seven days. Coincident with the improvement already noted the child began to take his feedings better, so that at the end of three and one-half weeks he had gained 15 ounces (425 Gm). When discharged after six and one-half weeks he weighed 7 pounds 6 ounces (3,345 Gm). He looked well, his liver and spleen were just barely palpable and his hemoglobin was 85 per cent.

CASE 2—Child admitted at 3 weeks of age with fever, jaundice, pyuria, *Escherichia coli* sepsis and bacilluria. This was possibly the result of a nursery infection. He was treated for ten days with sulfathiazole. Drug was stopped because of toxic symptoms. Urine was clear of pus cells after four weeks.

I. B., a boy admitted to the Mount Sinai Hospital at 3 weeks of age because of fever and jaundice, was born at term weighing 9 pounds 1 ounce (4,110 Gm) after a seventeen hour labor. He developed fever on the third day of life but this quickly subsided, so that circumcision was performed on the eighth day and he was sent home two days later. On the fifteenth day he was irritable but four days later, when seen by a physician, he had symptoms of coryza and a temperature of 102 F. The following day he was afebrile but passed a number of loose green stools. On the day of admission jaundice was noted. It was reported that 2 other infants who were in the nursery at the time this child first developed fever were subsequently hospitalized elsewhere, one with a gastroenteritis and the other with jaundice and *Escherichia coli* sepsis. When admitted the patient was afebrile, moderately well developed and jaundiced. He weighed 9 pounds 2 ounces (4,140 Gm). His throat was slightly reddened. The liver edge could be felt 1 cm below the costal margin, but the tip of the spleen was not palpable. The umbilical stump was clean. The penis was that of a normal circumcised newborn infant. The hemoglobin was 88 per cent, the red blood cells were 5,000,000 and the white blood count was 36,200 with 76 per cent polymorphonuclear cells. No nucleated red blood cells were seen. The icteric index was 48 (acetone method). It was found that the R₁ factor was not responsible for the jaundice. Catheterized urine obtained on admission was cloudy, was positive for bile and albumin and contained many clumps of leukocytes and bacteria. On culture *Escherichia coli* was recovered from the urine and blood stream. Urine culture four days later again revealed *Escherichia coli*. Blood culture repeated at the end of the first week was sterile. On admission the blood urea nitrogen was 24 mg per hundred cubic centimeters. The cephalin flocculation test was negative. The child was given sulfathiazole orally for ten days. Blood levels of 39 to 98 mg per hundred cubic centimeters were attained. On one occasion when the blood level was 7.3 mg per hundred cubic centimeters, the urine contained 180 mg of free sulfathiazole per hundred cubic centimeters. The morning after admission the temperature again rose to 102 F and thereafter for five days slowly fell fluctuating between 100 and 102 F. Despite this the jaundice deepened, so that on the sixth day the icteric index was 160 (water) and 100 (acetone). Thereafter it rapidly cleared and four days later was normal. The pyuria persisted and though on the eleventh hospital day there were still a moderate number of clumped leukocytes in the sediment chemotherapy was stopped. This was done because the child had become extremely drowsy and the hemoglobin had fallen to 60 per cent. Although he continued afebrile and slowly became more alert one week later the urine still contained a faint trace of albumin and a moderate number of leukocytes, some of which were in clumps. At the beginning of the fifth week the urine was clear except for a faint trace of albumin. When discharged at the end of six and one-half weeks the child weighed 9 pounds 11 ounces (4,394 Gm) was alert and on physical examination was normal. He was reexamined three months later in the follow-up clinic. It was reported that he had been well, he had gained almost 6 pounds (2,728 Gm) and except for a very faint trace of albumin the urine was normal.

CASE 3—Illness started with fever at 13 days of age, five days after a ritual circumcision with resultant local inflammatory reaction. Pyuria was associated with *Escherichia coli* and an enterococcus. He was treated for fifteen days with sulfathiazole at which time the urine was clear except for an occasional leukocyte. After four weeks the urine was entirely clear.

M. K., a boy admitted to the Mount Sinai Hospital at 2 weeks of age because of fever, was born after a prolonged labor with the aid of forceps, weighing 6 pounds 15 ounces (3,153 Gm). On the eighth day of life a ritual circumcision was performed. Two days later the glans penis was noted to be dark blue. On the thirteenth day of life he developed fever. On admission he was a vigorous, well developed and well nourished infant weighing 7 pounds 2 ounces (3,231 Gm) with a temperature of 104 F. The abdomen was slightly distended. The umbilical stump was clean. The penis was red about the glans with some crusting over the meatus. The corona was red and indurated. Hemoglobin was 70 per cent and white blood cells were 24,000 with 85 per cent polymorphonuclear cells. The admission urine contained some albumin, numerous leukocytes and a few red blood cells. Culture of a clean catch specimen grew out an *Escherichia coli* and enterococcus. When repeated one week later both these organisms were again recovered, but after two weeks only the enterococcus and *Staphylococcus aureus* A were grown. Blood culture was sterile. Urea nitrogen was 23 mg per hundred cubic centimeters. Sulfathiazole was given orally and continued for fifteen days. Blood levels of 35 to 39 mg per hundred cubic centimeters were attained. Within twelve hours the temperature was normal and remained so. During the first week the urine continued to contain many white blood cells, but when the drug was stopped one week later there was only a rare cell in the urine. However it was not until almost two weeks later, four weeks after the onset, that the urine was entirely free from cells. The inflammation of the penis subsided a few days after admission, and when the child was discharged after five weeks he was well and had gained 2 pounds (907 Gm). He was reexamined six and one-half weeks later at which time the urine was normal except for a faint trace of albumin and he was symptom free.

COMMENT

As already mentioned, Craig³ reviewed the case histories of 53 newborn infants whose urine contained 5 to 140 white blood cells per high power field. Two thirds of these were boys. The onset of their illness was usually indefinite, though he found prolonged anuria, especially when accompanied by fever, to be very suggestive of a urinary infection. However, as a rule there was little in the clinical picture to direct attention to the genitourinary tract, and systemic signs predominated. Fever was common, although a few cases had an afebrile course. Convulsions were of grave significance. Recovery was usual. The average duration of illness when treated with fluids and diuretics was six weeks. Recurrence was noted rarely. The subsequent general health of these children was not impaired. Sauer,⁴ as a result of a study of 12 cases thought that a nonthriving newborn male infant with gastrointestinal symptoms was the most common clinical picture. His cases responded within six weeks to diuresis and alkalization of the urine.

The 3 patients present an element of interest in that they were all boys and each showed symptoms before they were 3 weeks of age. Case 3 is most easily understood and is representative of cases of this syndrome which have been reported. The onset of fever a few

7 Pater-on Donald. Lancet 2: 1186 (Nov. 25) 1931.

days following an infected circumcision should quickly suggest the possibility of an ascending urinary tract infection. The contact of patient 2 with 2 other children during the immediate neonatal period who later became ill, one with a gastroenteritis and the other with an *Escherichia coli* sepsis and jaundice, suggests strongly the possibility of a nursery infection and hematogenous spread to the urinary tract. Patient 1, who was admitted because of failure to gain weight after a number of formula changes and some diarrhea, comes closest to presenting Sauer's typical picture of pyuria of the newborn. Although the disease is in general benign, this case with the development of severe uremia serves to emphasize some of its potential dangers.

The occurrence of jaundice as a complication of pyuria has been pointed out by many observers and is of interest as it may be a dominating symptom of the clinical picture. It is presumed to be due to focal necrosis of the liver.⁸ It may be present as a part of a severe general sepsis, but, as has been noted by Finkelstein,⁹ even though very deep jaundice is evident it may disappear with great rapidity. An example of this type was observed by one of us. A boy developed gastrointestinal disturbance at the age of 3 months, became very deeply jaundiced and had high fever. An examination of the urine in a test tube showed that a third of its volume was pus. The culture of the urine showed *Escherichia coli*. Blood culture was sterile. Under alkalinizing therapy the child recovered, though it was several months before the urine was entirely free from pus. The child was carefully followed for many years and never again showed any urinary disturbance. At the age of 17 years he was perfectly well. Of interest was the enormous amount of pus in the urine, the depth of the icterus and the relatively rapid recovery.

Two of our 3 patients were jaundiced. In case 2 with sepsis jaundice and no apparent focus of infection, the occurrence of icterus immediately led to the suspicion of a renal involvement. In case 1 the jaundice was probably unrelated to the urinary tract infection but was rather a result of erythroblastosis fetalis. The importance of making this distinction is obvious if transfusions are to be given.

All of these patient's leukocyte counts were elevated and reflected their infection. Their urine showed albumin and great numbers of pus cells often in clumps. In this small group, like most of the cases already reported, *Escherichia coli* was the offending organism. Because of this, sulfathiazole was given as well as other supportive measures.

The so-called atypical *B. coli* recovered from patient 1 has been described in that case report. That there are many strains of *Escherichia coli*, each of which has a slightly different behavior, has been recently emphasized in studies of the effectiveness of sulfonamides.¹⁰ It has been shown that although sulfathiazole is effective against all strains of the organism, the concentration of drug needed before this becomes apparent varies from strain to strain. With this in mind an *in vitro* test of the susceptibility of the organism recovered in case 2 against sulfathiazole was performed for us by Dr. Lotte Strauss. She reported that 2 mg. of sulfathiazole per

hundred cubic centimeters was found to exert a good bacteriostatic action on a broth culture inoculated with 2 drops of a 10-8 suspension of organism and read after twenty hours' incubation at 37 C.

That sulfathiazole is effective in this disease is apparent when it is recalled that in the 2 cases treated for two weeks or more there was definite improvement at the end of the second week. At that time only an occasional pus cell was found in the urine. This contrasts strikingly with the five to six weeks needed for recovery before the use of sulfathiazole.¹¹ Newborn infants tolerate the drug well. The dosage used with these children varied between 0.1 and 0.2 Gm. per kilogram of body weight in twenty-four hours. Although the medication had to be stopped in case 2 after ten days because of the pronounced lethargy of the patient, it is not at all clear that this was not the result of cholemia. Even with this shortened course of chemotherapy the drug was probably effective in helping to cure the sepsis.

Because some of these cases have been associated with organic obstruction to the urine outflow,¹² several attempts were made in each of the 3 children studied to visualize the upper urinary tract with intravenous pyelography. Not one of these was successful, chiefly because of gas in the intestinal tract. However, it is unlikely that the majority of patients have very severe obstructions, since without surgical intervention the greater proportion of patients get well. Stasis due to some growth disturbance or nervous imbalance, perhaps as a result of local immaturity, would seem to fit the clinical picture better.

In the few fatal cases the pathologic changes have been slight. They have been most often found in the kidney substance. A suppurative interstitial pyelonephritis was found in a number of cases by Wilson and Schloss¹³ and also by Craig.³

SUMMARY

Of 3 cases of pyuria occurring in newborn boys, 1 was associated with uremia and failure to gain weight, 1 with jaundice and *Escherichia coli* sepsis and 1 probably was secondary to an infected circumcision. All boys were treated with sulfathiazole and recovered. The drug seemed to accelerate this recovery. The physiologic changes taking place in the neonatal period appear to be conducive to the peculiarities of urinary tract infection in this age group.

Diagnosis of Gout—Gout is a distinct clinical entity and should be differentiated clearly from the other arthritides. It is most likely that many cases of nongouty joint diseases were mislabeled gouty rheumatism in ancient and medieval times. This error should be committed on a large scale no longer. Confronted, then, with a suspected case of gout, whether acute or chronic, what shall be our way of approach? Not the easy and hazardous path of lightning diagnosis affected by those who plume themselves on their so-called clinical 'instinct,' but the slow laborious route of clinical 'observation' that leads more surely to the vantage ground of the truth, this assuredly in all diseases, but in none more so than in joint disorders, whose outward resemblances so oft hark back to inward disparities.—Talbot, John H. *Gout*. TREATMENT OF ANKLE SPRAIN

OBSERVATIONS IN MORE THAN FIVE
HUNDRED CASES

FIELD COMDR PAUL L. MCMASTER
MCV(S) USNR

Ankle sprains may cause much disability and often do in military industrial and other activities. Observations on various types of treatment in over 500 cases closely studied are presented. More than 200 of the patients were treated with injection of procaine hydrochloride solution and over 200 were strapped with adhesive tape. Sixty-eight received either no treatment or cold and hot packs or an elastic bandage for support.

The patients treated were men in active military service mostly in the late teens and twenties, although some were in the fourth, fifth and sixth decades. Eight women were treated. All degrees of sprain from minor to severe were seen but in each case the condition was sufficient to cause the man to seek relief either immediately or within the first day or so.

The most common ligament sprained was the anterior talofibular which occurred in over 90 per cent. Other ligaments in order of frequency and usually in association with the foregoing were the calcaneofibular, anterior interior tibiofibular, medial or deltoid posterior tibiofibular and posterior interior tibiofibular.

Roentgenograms were made almost routinely. No cases of fracture including sprain fracture are included. Diastasis of the lower tibia and fibula was not demonstrated even though local signs pointed to injury of the tibiofibular ligaments.

Various treatments were used for comparison. Over 200 patients were strapped with adhesive tape, some of whom were sent immediately to duty and the others were instructed to limit weight bearing and protect the ankle by either complete bed rest or by use of crutches or cane. Bed rest without weight bearing for a day or more with initial cold applications and later hot to reduce swelling was tried in 22 cases. Twenty-eight patients were given only an elastic bandage support while 18 with mild to moderately severe sprains were given no treatment and both latter groups were sent back to duty immediately.

More than 200 patients received local injection of procaine hydrochloride and with but a few exceptions were sent to duty immediately.

The technic of local injection has been described by Leriche¹ and others. Fracture is excluded by radiographic study. The sprained ligaments indicated by tender points are determined by palpation. An antiseptic is then applied to the skin. Two per cent procaine hydrochloride solution without epinephrine is used routinely and with it a wheal is made in the skin over the site of injury with a fine needle. The latter is replaced by a larger needle and the underlying injured ligament is injected. All tender points, whether proximal, distal or intervening portions of the ligament, are injected. A search is then made for tender areas in other ligaments

and these are each carefully injected until no tender or painful areas remain either with palpation or ankle and foot motion. The amount of procaine solution varies from around 10 to 20 cc. There is no hesitancy to use an ounce or more if necessary. Next an elastic bandage is wrapped snugly around the ankle and the patient is requested to walk around the room. If any pain is experienced further injection is done. The patient is then returned to activity with instruction to use and move the foot and ankle normally except for running and jumping. Also it is stressed that while sitting as at a desk or table the foot should be moved and not kept immobile in one position even for short periods. The elastic bandage is to be removed and rewrapped by the patient in one to two hours to prevent possible circulatory constriction. Daily and periodic return for check-up is required in all cases.

RESULTS AND COMMENT

Invariably patients whether with moderate or severe sprain and almost irrespective of the type of treatment given who were immediately sent back to routine activity and use of the part did much better than those who were put at rest for a few days with limited or no use of the part. The ones who were inactivated for one or more days by either being put to bed for cold and then hot applications or having ankles taped and cautioned to bear limited or no weight on the leg with the aid of crutches or cane were often disabled for periods of a few days to two or three weeks. One patient was disabled eight weeks. The ankles in the latter cases usually remained swollen, tender, stiff and painful and only gradually did these conditions subside.

The patients who either received no local treatment or were given only an elastic bandage for support but were returned immediately to duty to use and move the part had remarkably little disability, which if any lasted not more than a few days. This was also true for the majority of patients who were only taped and sent back to duty immediately. Swelling, pain and stiffness rapidly disappeared and disability of longer than two to three days was not common if the man continued his weight bearing and moved the ankle as instructed.

Injection of procaine hydrochloride solution and immediate return to duty gave routinely the best results. Disability was entirely absent in many and rarely lasted over twenty-four or forty-eight hours in the others. Several patients were intentionally inactivated with bed rest and crutches after injection for several days, and these had somewhat similar prolonged disability periods to patients who were treated with other local methods and kept inactive. A few apprehensive patients failed to follow instructions of continued use and motion after injection and these also recovered slowly. Patients who had some complication such as an underlying chronic arthritis of the ankle or a pulled muscle (usually peroneal) experienced delayed recovery. Some patients were not permitted to return to hazardous activity, such as parachute jumping for a week to ten days even though they felt able to.

Pain rarely recurred after injection and in no case was reinjection necessary. Motion of the ankle on the day following injection was often normal or nearly so. Forced passive motions especially inversion and eversion were apt to be painful for several days. Swelling was less the next day and progressively decreased usually disappearing even in the severe cases within five to ten days. Tenderness of injured ligaments to

palpation lasted, on an average, three to five days, even though there was no pain with active motion. Erythema, local or diffuse, over foot and toes often lasted seven to fourteen days.

Success of the injection procedure depends on two factors: first, total elimination of pain and tenderness by complete adequate initial intraligamentous injection and, second and more important, continued use and motion of the foot and ankle. If the injection fails to relieve pain the patient may limp and not use the part normally, or if he is apprehensive and does not use or move the part as instructed, stiffness, swelling and pain result and persist.

It appears that by maintaining active use and motion, circulation is improved, tissue metabolism and repair are thus enhanced and extravasated blood and serum tend to be mechanically expressed from the region, hence the swelling and stiffness with resultant pain consequent to stasis are materially reduced. Leriche explained the benefit of local injection for sprains on a basis of eliminating pain impulses and thus preventing the vasomotor change, which at first is a passive vasodilatation and later active. This explanation is not the sole answer, for it does not explain the excellent results which can be obtained by other methods, such as taping, in cases in which no injection is done but in which, if immediate and continuous use and movement of the part are done, recovery is rapid.

Many of these patients have been seen and examined after several months and all had normal ankle motion, no pain, no swelling and no tenderness.

The maintenance of normal ankle motion, namely flexion and extension, after injection does not aggravate the injured lateral or medial ligaments and thus normal active use is not contraindicated. Strenuous running or jumping, however, are inadvisable for several days because of the chance of "turning" the ankle again and thus reinjuring the ligaments.

Patients with old untreated sprain of a few to several days' duration are treated either with taping or with procaine hydrochloride injection and returned to activity with instructions to keep moving and to use the part. Recovery in these cases is as a rule slower but even so it is facilitated with active use and motion.

Cozen and Hollombe² used the ethyl chloride spray and reported satisfactory results in 8 cases of ankle sprain. Among those who have used and reported good results with local injection of sprains are Sperber and Sabatino,³ Kiser,⁴ Frankel,⁵ Ball⁶ and Alexander.⁷ Frankel recommended avoidance of exercise for a few days, while Ball had his patients use crutches after injection for three days. Alexander, who reported over 500 cases of ankle sprains, advocated, in addition to injection of procaine hydrochloride, strapping the ankle with adhesive tape and then immediate use of the part. He concluded that his results were superior by this method than by any other. His observations are substantiated by the results herein reported, especially that part having to do with immediate use.

7 Alexander, H. H., Jr. Treatment of a Sprained Ankle, *Am. J. Surg.* 50: 581 (Dec.) 1940.

SUMMARY

More than 200 patients with ankle sprain were treated with injection of procaine hydrochloride and more than 200 with adhesive tape strappings. Others received no treatment, while still others were put to bed for cold and hot applications. Irrespective of the type of treatment, patients who returned immediately to normal activity and used and moved the foot and ankle improved much more rapidly than those who did not.

Injection with 2 per cent procaine hydrochloride solution into the injured ligaments followed by normal activity gave uniformly the best results. These patients, following complete elimination of pain and tenderness by injection, continued immediate use of the part, avoiding only especially strenuous activity as hard running or jumping.

CONCLUSIONS

Immediate and continued active motion and use of a sprained ankle and foot almost irrespective of any local treatment definitely hastens recovery.

The most satisfactory adjunct in the treatment of ankle sprain in order to maintain motion and use of the part is the complete elimination of pain by the injection of 2 per cent procaine hydrochloride solution into the injured ligaments.

A SURVEY OF METHODS FOR ARTIFICIAL RESPIRATION

BERNARD D. ROSS, M.D., PH.D.
CHICAGO

A survey of the commonly used methods of resuscitation from acute asphyxia is essential to the evaluation of their efficacy. Such a survey has been in progress for three years, beginning in 1940. It was deemed necessary because of the existing controversy and con-

TABLE 1—Sources of Case Reports

fusion regarding the relative values and dangers of the different methods. Although the Schafer pressure method has received most widespread acceptance, other methods are taught and used by various groups. For example, the United States Coast Guard advocates the use of the Howard modification of the Sylvester method when a sufficient number of operators are present. Organizations such as the Chicago Fire

Funds to carry on this work were provided by the Council on Life Therapy of the American Medical Association.

REMARKS

U S C G
Commanding Officer

INSTRUCTIONS

1 This form shall be submitted by all units on each occasion of resuscitation of the apparently drowned, whether or not resuscitation is successful. It shall be prepared in quadruplicate. The original and one copy shall be forwarded to headquarters via the district commander and a copy shall be included for his files. A copy shall be retained in the files of the unit concerned.

2 Under Remarks relate in detail the circumstances of the accident, describe each step taken in restoring the patient and state the successive signs of returning life shown while resuscitation was being performed. If the attempt to revive the patient was unsuccessful obtain the opinion if available of physician or local health officials as to whether or not patient was dead on removal from the water and if death was due to causes other than drowning. State cause of death if known.

3 If necessary use separate sheets of paper 8 by 10 1/2 inches in size for the submission of additional remarks or in answer to any of the questions on page 1 or the form.

information a case report form was devised. The Chicago Fire Department and the Chicago Health Department used this form in submitting reports on all cases as they occurred. The Los Angeles Fire Department and the United States Coast Guard sent in data on their regular departmental forms. The information requested in the case report forms is shown herewith. All cooperating organizations agreed to send in reports of all cases of asphyxia as they occurred, regardless of whether revival or death occurred in each instance.

Material presented in this paper represents reports of cases of asphyxia occurring in 1940, 1941 and 1942. Table I shows the number of cases from the various

sources and the distribution of the cases reported into groups. The patients who were asphyxiated because of heart disease were considered separately because of the poor prognosis in such cases. It was also found necessary to tabulate separately patients respiring spontaneously (gasping, severe dyspnea and the like) at

Asphyxia neonatorum is the most frequent type of asphyxia in which revival occurred. Next come immersion, carbon monoxide and other less frequently occurring causes.

Table 3 includes all cases of impaired respiration in which survival occurred. In each case breathing

the start of treatment in contrast to those in whom spontaneous respiration had ceased. Results in the latter group are obviously more significant.

Table 2 represents the patients in whom spontaneous respiration had completely ceased by the time artificial respiration had been started and who survived. A total of 133 cases are presented in this group. The two methods employed most frequently are the E & J resuscitator and the Schafer prone pressure method

had not stopped completely at the start of treatment. There are 915 cases in this group, in 792 of which the E & J inhalator was used. Acute cardiac conditions (coronary occlusion, acute cardiac dilatation and the like) were the most frequent causes of asphyxia in this group, numbering 354 cases.

Cases of carbon monoxide poisoning numbered 147, followed by the less frequent causes that are listed in the table.

Table 4 represents cases in which death occurred. In all of these cases there is no evidence that thirty minutes or more had elapsed between cessation of breathing and the start of artificial respiration. Seventeen patients with cardiac lesions and 1 whose illness was undiagnosed died although they were breathing when treatment was started. Thirty minutes was selected as the maximum interval between cessation of breathing and the start of artificial respiration, although a maximum of more than fifteen minutes is probably not entirely consistent with physiologic evidence. A thirty minute limit was chosen because owing to the emergency nature of the cases reported and the inherent confusion which naturally results, errors of as much as 100 per cent can easily be expected in the estimation of time by onlookers or participants and because periods of as long as one hour or more have been reported in the literature.¹ Of the 133 cases of survival presented in this report the maximum time between the

In its present state this survey does not present such data. Thus of 74 cases of asphyxia neonatorum (33 survivals and 41 deaths) in which spontaneous respiratory rhythm was not present at the start of treatment 72 were treated by the E & J resuscitator and none by the Schafer method. In all the data given in this report there are too few cases in which the Schafer and other manual methods were used. However, the material presented here does reveal the following:

1 There are 66 cases of acute asphyxia in which a mechanical method of artificial respiration with alternate blowing and sucking resulted in revival. None of the patients, 33 of whom were newborn infants, showed evidence of injury as a result of this procedure.

2 There are 35 cases in which the Schafer prone pressure method was successful in resuscitation. In none of these cases nor in any of the additional 215 cases in which the Schafer prone pressure method was used (either entirely or in part) was there any report of

* In all cases there is no evidence that thirty minutes or more had elapsed between cessation of breathing and start of artificial respiration. Subscript figures indicate cases in which patient was still breathing when treatment was started.

onset of asphyxia and the start of artificial respiration was fifteen minutes.

In table 4 933 fatalities are presented. The great majority of these (590) were victims of cardiac ailments. Other causes include immersion, asphyxia neonatorum and other less frequently occurring conditions. Use of the E & J resuscitator was the most frequent method employed. The second most frequent method was the use of the E & J resuscitator preceded by the Schafer method. This represents instances in which a passer-by had started the Schafer method and firemen subsequently took over with the E & J resuscitator.

RESULTS

It is evident that in spite of the large number of cases presented (no similar group of cases has previously been reported in the literature) it is not yet possible to make a comparative evaluation of the different methods that are listed. Theoretically, in order to compare the efficacy of two methods data should be presented in which each of the methods is used in a significant number of cases in each type of asphyxia

fractured ribs. Such injuries have been said to be a possible result of improper use of this method.

3 No instance of revival was reported in which more than fifteen minutes elapsed between the cessation of breathing and the start of artificial respiration.

4 Of 584 patients with asphyxia and complete cessation of respiration due to cardiac causes, only 11 survived. Of 371 patients with impaired respiration due to cardiac dysfunction, 354 survived and 17 died. According to the data the Chicago Fire Department and the Los Angeles Fire Department treat more cases of asphyxia due to circulatory failure than any other cause.

This paper is not presented as a final summary but as a progress report. It is hoped that in the future additional organizations using some form of artificial respiration routinely will cooperate. Reports of instances in which the Schafer or some other manual method of artificial respiration is used will be particularly helpful. A series of reports received from any life saving organization should include all patients treated by that organization within a given period. Report forms will be sent to any organization on request.

STAB WOUND OF THE HEART

REPORT OF A SUCCESSFUL OPERATION

MANDEL WEINSTEIN, M.D.

LONG ISLAND CITY, N. Y.

Modern surgery has contributed many outstanding scientific achievements the most recent of which include successful operations on the organs of the chest. This has been made possible in great part by a better understanding of the problems caused by an altered physiology of the respiratory and cardiovascular systems. As a result newer and better methods in anesthesia have been devised and operative technique has been greatly improved. Today the morbidity and mortality of thoracic surgery is not much different from that of surgery elsewhere in the body. In addition, the use of the sulfonamide compounds has greatly reduced the incidence of fatal postoperative respiratory infections—complications more frequently seen in chest surgery.

Suturing of heart wounds is a relatively recent procedure. The first report in the literature of a human heart to be sutured was by Cappelen¹ in September 1895. However this resulted in a mortality, as did the case of Farina² in March 1896. Rehn³ of Frankfurt recorded the third case of heart suture in September 1896 and this operation resulted in recovery. As was to be expected many more successes soon were reported once the practicability of the operation was established.

The percentage of reported recoveries, however, must not lead one to believe that the mortality has been low.⁴ Unquestionably the large number of fatal cases has not been publicized while the individual favorable cases usually have. Most observers believe that the mortality has been 50 to 60 per cent. Bigger⁵ mailed a questionnaire to 427 surgeons, all members of the American Association for Thoracic Surgery, the American Surgical Association and the Southern Surgical Association. According to the answers received, 128 patients were operated on for wounds of the heart chambers and coronary arteries. Sixty-three patients recovered and 65 died, a mortality of approximately 50 per cent. Therefore, even though stab wounds of the heart are infrequent occurrences, many a life can be saved by an accurate diagnosis, an early, well planned operation and a thorough understanding of the treatment of post-operative complications. Herewith is reported a lacerated wound of the right ventricle successfully sutured

REPORT OF CASE

History—J. D., a boy aged 14 years, was admitted to St. John's Long Island City Hospital, Nov. 25, 1941 about a half hour after he had been stabbed. The weapon used was vaguely described as a pen knife of unknown length. The patient collapsed immediately after the stabbing and fell to the ground. A large amount of blood loss was not evident at the scene of the accident or on the patient's clothes. Two passers-by who happened to witness the stabbing brought the patient to the hospital.

Examination—On admission the patient appeared to be thin and undernourished and exhibited extreme pallor of the skin and mucous membranes. He was in shock but conscious and well oriented. The pulse was 120 to 130 a minute and regular

but barely perceptible. The systolic blood pressure was 60 mm of mercury and the diastolic pressure 40 mm of mercury. Respiratory difficulty was not evident. To the left of the sternum a 1 inch vertical lacerated wound was seen at about the level of the fourth intercostal space. The wound bled very little externally. The surrounding subcutaneous tissues were emphysematous but not ecchymotic. The left side of the chest anteriorly showed diminished breath sounds. The abdomen was soft and free from tenderness and seemed to be uninvolved. An emergency blood count showed 4,490,000 erythrocytes and 90 per cent hemoglobin, or 131 Gm per hundred cubic centimeters of blood. Examination of the precordial region was interesting, since heart sounds of fairly good quality were heard. Close inspection of the veins of the neck revealed definite enlargement and distention.

An immediate fluoroscopic examination by the roentgenologist, Dr. Joseph Sullivan, disclosed "no cardiac motion visible under the fluoroscope." Therefore the diagnosis of cardiac hemorrhage with tamponade was made, and immediate operation was decided on.

Operation—Anesthesia was by local infiltration and regional intercostal nerve block with 1 per cent procaine hydrochloride. The incision was U shaped, with the base to the left over the costochondral junctions and the anterior rib stumps. The curved portion was placed at the left sternal border extending from the third to the sixth costal cartilage. The superficial stab wound was included in the center of this flap. The incision was carried through skin, subcutaneous tissue and extracostal muscles down to the plane of the cartilages and ribs. The fourth, fifth and sixth costal cartilages were completely removed up to the sternum, together with 1 to 2 inch segments of corresponding ribs. All this was accomplished subperichondrially and subperiosteally.

The internal mammary artery and vein were doubly ligated above and below and then sectioned. At this point, one could see clearly that the wound penetrated the left pleura first and then the pericardium. The pericardial fat was swollen and extensively ecchymotic. The opening into the pericardium and pleura was now enlarged, and large clots could be seen in the pleural cavity. No lacerated pulmonary tissue was noticed. This was particularly searched for because of the subcutaneous emphysema. Incision into the pericardium resulted in the expulsion of several large clots with liquid blood. A hurried inspection of the heart disclosed a 2 to 3 cm wound of the right ventricle extending through the entire ventricular wall into the chamber. The wound was situated at the junction of the middle and lower thirds of the right ventricle near the interventricular septum. The heart was bleeding actively from the wound, but the beats were regular.

To control the bleeding the tip of the left index finger was placed lightly over the lacerated wound but not into it. A traction suture of silk was inserted through the cardiac apex according to the method first described by Beck⁷ in his work on experimental animals.

This permitted an assistant to steady the heart for suturing. Two figure-of-eight sutures of fine black silk were placed through the full thickness of the ventricular wall, completely closing the opening and controlling the hemorrhage. The ventricle was too thin in this region to obtain satisfactory closure of the laceration without carrying the suture material into the chamber. Clots and liquid blood were hurriedly removed from the pericardial and pleural sacs, but an attempt was not made to remove all of them. The lingula and anterior edge of the lower lobe of the lung were loosely sutured to the anterior margin of the pericardial incision. Drainage of blood and serum from the pericardial sac into the left pleural cavity was thus made possible by the incomplete closure of the pericardium. The rest of the wound was closed with interrupted chromic catgut sutures for the muscle and fascia and interrupted black silk sutures for the skin.

The anesthesia was good and the patient cooperated fully in spite of his youthful age. Only when the pericardium was incised and the clots evacuated did he become restless and

From the Surgical Service of St. John's Long Island City Hospital. The medical collaboration of Dr. E. W. McIave, director of the medical service, contributed to the favorable outcome in the case reported.

disturbed. However, this was not troublesome enough to interrupt the operation. Throughout the procedure 500 cc of citrated blood was administered. The entire operation including the time for induction of the anesthesia, consumed about forty minutes. The patient left the operating room in much better condition than when he entered, his pulse being only 108 beats a minute and of much better quality.

Postoperative Course.—After the patient's return to bed from the operating room his temperature by rectum was 101.8 F and his respiratory rate 40 a minute. He was immediately placed in an oxygen tent for relief of anoxia. During the first night more citrated blood was given making a total of 850 cc of blood administered thus far. On several occasions the patient complained of severe precordial pain for which several doses of morphine sulfate had to be given hypodermically. In the morning it was possible to give 1 Gm doses of sulfathiazole and sodium bicarbonate by mouth every four hours since the patient was retaining fluids well without any symptoms of nausea or vomiting. Throughout his first postoperative day his breathing was labored, with a respiratory rate never below 40. At times he was so insistent about remaining outside of the oxygen tent that his wish had to be granted. However, no ill effects were observed and later on we were able to persuade him to be placed in the tent again. The precordial pain was particularly distressing and was his only complaint.

Three days later (twelfth postoperative day) aspiration was again done, resulting in the removal of 660 cc of the blood tinged fluid. Laboratory studies failed to detect bacteria or pus cells in the fluid.

On the seventeenth postoperative day the patient had severe pain over his heart, left shoulder and neck, respirations were rapid and cyanosis was present. This condition persisted for forty-eight hours during which time the temperature rose from 101 F to 103 F. Crepitant rales were elicited in the left base posteriorly. Roentgenograms (fig 2) showed less fluid but the lung seemed to be reexpanding. The pericardial shadow seemed widened and displaced to the right, indicating the possibility of pericardial effusion. Electrocardiographic studies were not helpful. However, aspiration of the pericardium yielded neither fluid nor blood. I believe that what appeared to be a widened pericardium was only a pericardium rotated to the right because of lack of support of the chest wall. Costal cartilages and ribs had not yet regenerated and this support was lacking.

Fortunately this acute episode of fresh pulmonary infiltration lasted only five days, after which time the patient suddenly and rapidly improved. Dyspnea, fever and rapid pulse subsided quickly, and from this time on the patient enjoyed a smooth convalescence. His improvement coincided with a stiffening of the chest wall in the operative region. He left the hospital Jan. 24, 1942, apparently entirely recovered.

Fig 1—Partially collapsed left lung and fluid in the left pleural cavity thirty-six hours after the operation. The mediastinum is not shifted to the right.

Fig 2—An apparently widened mediastinum suggestive of an effusion into the pericardial sac twenty-three days after the operation. Exploratory aspiration failed to reveal pericardial fluid or blood. A softened chest wall in the operative region permitted retraction and rotation of the parietal pericardium thus accounting for the confusing picture.

Fig 3—Appearance two and one-half months after the operation, practically normal except for thickened pleura in the left side of the chest.

On the second postoperative day his condition improved sufficiently to permit an electrocardiogram to be taken. These studies will be discussed at length later in this report. Three hundred cc more of blood was given. The temperature remained around 102 F, the pulse rate 130 and regular and the respiratory rate not less than 34 a minute. His blood pressure was 118 mm systolic and 74 mm diastolic. A bedside roentgenogram (fig 1) revealed a reexpanding left lung with a moderate amount of fluid in the left hemithorax, and there was a slight mediastinal shift to the right. The operative wound was inspected and found clean. Definite paradoxical movement of this area with respiration was noted.

From the third day on improvement was slow but progressive. A serum reaction from tetanus antitoxin caused generalized adenitis and orbital edema. Fluid accumulated in the left pleural cavity; the lung remained partially collapsed and paradoxical motion was still present over the precordium.

Nine days after the operation enough pleural fluid collected to require aspiration. This procedure was carried out in the seventh interspace in the midscapular line whereupon 260 cc of thin blood tinged fluid was removed. On bacteriologic studies this material was reported sterile with an occasional mononuclear cell and a rare polymorphonuclear cell. This pleural decompression resulted in less dyspnea and an improvement in the patient's color. Even though the amount of fluid removed was small, relief was considerable since the patient's chest was of small capacity.

He was readmitted twelve days later, on February 4, complaining of fever and chest pain. Physical examination and roentgen studies disclosed a limited area of consolidation in the lower part of the left lower lobe with a small amount of fluid. He responded favorably to sulfadiazine therapy and in five days was free from fever and fully recovered. He was discharged from the hospital for a second time on March 12.

Follow-up examinations revealed a well regenerated chest wall with only a small soft area in the center of the operative wound. For this he wears a small protective pad of felt to avoid accidental injury. There are no complaints of precordial pain or shortness of breath. He attends school and runs and plays as well as his friends do.

ELECTROCARDIOGRAPHIC CHANGES

The patient's past history disclosed that he had never been operated on or stricken with any serious medical illness. Therefore, it can be assumed that the boy had a normal heart prior to the accident and that if electrocardiographic studies had been made they would have been normal.

As indicated in figure 4, electrocardiograms were taken after the operation at intervals of thirty-six hours, three days, seven days, twenty-three days, thirty-two days and one hundred and fifty-two days. The find-

mgs parallel those reported by Davenport,⁸ Warthen⁹ and others. Our patient's records show the typical progression of changes seen in infarction on the anterior wall of the heart. Thirty-six hours after operation the

Fig. 4—Typical progression of changes postoperatively seen in infarction on the anterior wall of the heart. Thirty-six hours after the operation the tracing was typical of the acute phase of infarction. However, only one day later a second tracing demonstrated less displacement of the ST segment.

tracing was typical of infarction of the anterior wall in the acute phase. However, only one day later a second tracing demonstrated less displacement of the ST seg-

Fig. 5—The laceration penetrated through the entire thickness of the anterior wall of the right ventricle. It was possible to place the two interrupted silk sutures in the wound edges without involving any vessels.

ment. From this period on ST segments showed even less elevation together with those other changes indicative of progressive healing of the infarction. The last

electrocardiogram, taken one hundred and fifty-two days after the operation, was practically normal except for a small Q wave in leads 2 and 3 and inversion of the T wave in leads 3 and 4. However, these may be considered normal changes in children.

Should it become necessary to include branches of the coronary vessels in the suturing of lacerated wounds of the heart, abnormalities in the electrocardiogram may persist for many months.¹⁰ Olm and Hughes¹¹ described abnormalities in the fourth lead due to encirclement of the left anterior descending coronary vessels by the sutures.

Mention must be made here that heart wounds of small size, such as ice pick puncture wounds manifest electrocardiographic disturbances of lesser degree and also of shorter duration. On the other hand, large

Fig. 6—Appearance of patient about nine months after the operation. The wound is well healed and only a minimal amount of softening of the chest wall is present. The patient is free from any symptoms.

lacerations penetrating the heart wall completely and requiring more than one suture interfere to a greater degree with conduction and myocardial circulation.

COMMENT

Diagnosis—The classic signs of tamponade may not always be present. My patient showed only a slight diminution in the intensity of the heart sounds and very little shift of the maximum apical beat from the normal position. This can be explained by the thin chest wall and the effective plugging of the heart wound by clot and blood. However, fluoroscopy clearly demonstrated an immobile heart.

Warthen⁹ describes a case in which tamponade was not present. The clinical picture was one of profound

shock and severe hemorrhage, heart sounds could be heard but only feebly. In fact the preoperative diagnosis was severance of the internal mammary vessels with active bleeding. At operation the pleural cavity was the seat of a massive hemothorax, since the pericardium was decompressing itself into the left pleural cavity.

Anesthesia—Patients in such grave states of shock tolerate surgical procedures best when local anesthesia is used. This can always be supplemented by inhalation anesthesia if the patient's behavior warrants it. In the literature mention has been made of the restlessness under local anesthesia at the time of opening the pericardial sac and relieving the cardiac compression. This procedure was not serious in my case and the operation proceeded without incident. I believe that the choice of anesthesia should follow the same principles as are applicable to operations elsewhere in the body; the surgeon should utilize that method which in his hands has given the best results.

Incision—Blalock¹² reported a successful case in which he used a sternum splitting incision, later approximated by encircling sutures of silver wire. This incision was originally described by Cutler¹³ in Dean Lewis's Surgery, but thoracic surgeons in general condemn its use. The procedure is time consuming and shocking for the patient and fails to afford proper exposure, since lacerations of the pleura usually accompany stab wounds of the heart.

The flap incision used in this case affords a quick approach with adequate exposure. Subperichondrial and subperiosteal removal of the costal cartilages and ends of the ribs permits the regeneration of a stiff chest wall. This is important because the parietal pericardium derives considerable support from its attachment to this region of the chest. If this support is missing, the result is a more mobile mediastinum, definite paradoxical breathing, a rapid respiratory rate and a lessened negative pressure in the pleural cavity with delayed reexpansion of the left lung. Regeneration of these structures takes approximately four weeks. Figure 2 illustrates the rotation and displacement of the pericardium to the right simulating the shadow of pericardial effusion. However, exploratory pericardial aspiration was negative, disproving the possibility of pericardial effusion. At this time there was an insufficient amount of fluid in the left pleural cavity to cause a shift of the mediastinum to the right. But approximately four weeks after operation, the chest wall stiffened and the symptoms of tachypnea and respiratory distress suddenly ceased. Roentgenographic studies showed the mediastinum returning to the normal position with an increased reexpansion of the left lung.

Suturing of the Heart Wound—Heart muscle is friable and merits gentleness in handling.¹⁴ Mamikonoff¹⁵ relates an unusual experience in suturing a lacerated heart. He used silk, and on both occasions the sutures cut through. After these failures he applied a flap of pleuropericardial septum over the opening thus effectively plugging the bleeding area.

Even though many surgeons have used catgut successfully for closure, the use of silk, nylon or cotton is

preferred. There is less local foreign body reaction and a smaller area of fibrotic tissue results. Of course the suture material should be as fine as is consistent with adequate tensile strength. Mamikonoff states that he used "thick silk sutures which cut through." This may account for the failure of his sutures to approximate the heart wound without cutting through the muscle edges.

If an artery or its branches are close to wounds, every effort should be made not to include the vessels in the sutures. In an ingenious manner of suturing, Beck¹⁶ describes a method for approximating wound edges without involving vessels. He refers to the case of Olm and Hughes¹¹ and shows diagrammatically how inclusion of the vessel in the sutures could have been avoided.

Drainage—Instances are mentioned in the literature wherein cardiac tamponade recurred following an apparently successful operation for a stab wound. To avoid such complications pleuropericardial drainage should be instituted. Since most patients also demonstrate a pleural wound, such drainage can be conveniently established. In the case reported here in addition to allowing drainage from the pericardial sac into the left pleural cavity the edge of the lung in the region of the lingula was loosely sutured to the anterior border of the pericardial opening. This provides a buffer between the heart and the chest wall and at the same time permits decompression of blood and clots from the pericardial sac.

External drainage is mentioned only by way of condemnation. Olm and Hughes¹² summarize the subject well with the following arguments:

- 1 Drains are irritating and increase the amount of pericardial effusion.
- 2 Drains invite infection.
- 3 Drains predispose to the introduction of air into the wound, causing "sucking" and all the other complications of an altered intrapleural pressure.
- 4 Drains increase the possibility of pericardial fibrosis with adhesions even though no infection is present.

Respiratory Complications—These are to be expected since the pleural cavity is entered in almost every case and the pericardium is intentionally drained into it. However, the use of the sulfonamide compounds locally and systemically can usually be relied on to combat such infections. In the case reported here several aspirations of the pleural space were necessary but no bacteria or pus cells were ever seen in the fluid. These simple aspirations of 150 to 300 cc. of fluid were sufficient to relieve the mediastinal and pulmonary embarrassment of this boy.

About five weeks after his discharge the patient was brought back to the hospital where a diagnosis was made of an infiltrative process involving the lower half of the left lung field, accompanied by a small amount of fluid ascending the lateral chest wall. Such a recurrence of the pathologic condition can be accounted for by the fact that the lung and pleurae were exposed to trauma and external infection. The delayed reexpansion of a collapsed lung, even with low grade infection results in widespread formation of fibrous tissue and peribronchial infiltration. The bronchi in the involved area of the lung may become thickened and distorted and their lumens narrowed. They are apt to drain their secretions incompletely, thus making the cough reflex

ineffectual. This accumulation of bronchial secretions blocks the airways, causing areas of atelectasis distal to the obstruction. The end result is the formation of patches of consolidation of various sizes distributed throughout the lung.

As for the pleural reaction, the formation of fluid is to be expected in almost all openings into the pleural cavity, accompanied by the usual changes in negative pressure and collapse of the lung. Lacerations of lung tissue are accompanied by bronchopleural fistulas, and these may be sealed temporarily or permanently. If fistulas remain open, severe contamination of the pleural cavity may follow since bronchi of medium and large size harbor many aerobic and anaerobic organisms. In this event an operation for empyema may be necessary. One should bear in mind the possibility of a pressure pneumothorax, because deflation at the proper time may be necessary as a life saving measure.

SUMMARY

1 The stab wound of the heart in the case reported was through the entire anterior wall of the right ventricle.

2 Pericardial effusion was suggested by postoperative roentgenographic studies. In reality, the softened chest wall permitted the mediastinum to fall away from the precordium, thus simulating a widening pericardium.

3 Serial electrocardiograms demonstrated tracings typical of an infarction of the anterior wall. In six to seven weeks electrocardiographic evidence of myocardial damage disappeared.

4 A recurrence of pleuropulmonary infection after discharge from the hospital responded favorably to sulfonamide therapy.

Clinical Notes, Suggestions and New Instruments

ACUTE AGRANULOCYTOSIS DUE TO ADMINISTRATION OF SUCCINYL SULFATHIAZOLE

STURE A M JOHNSON MD, ANN ARBOR, MICH

Cases of acute agranulocytosis due to the administration of sulfanilamide,¹ sulfapyridine,² sulfathiazole³ and sulfadiazine⁴ have been reported. A review of the literature reveals no cases of acute agranulocytosis due to succinylsulfathiazole. Because of the importance this drug has assumed in the treatment of gastrointestinal disease,⁵ it is important to present this case of fatal agranulocytosis.

REPORT OF CASE

R M Y, a white youth aged 19, a factory inspector, was admitted to the department of dermatology and syphilology of the University Hospital on April 4, 1942 complaining of a nonpruritic cutaneous eruption of six months' duration. The family history and the past history of diseases were noncon-

(Footnotes continued in next column)

tributory. The physical examination revealed a temperature of 98.6 F, a pulse rate of 80, a respiratory rate of 20 and a blood pressure of 120/80. The remainder of the physical examination was essentially negative except for the skin, which showed a dermatitis on the scalp and face, in the axillas, about the genitalia and on the extremities. The laboratory studies revealed that the urine was normal, the Kahn reaction negative, the hemoglobin 89 per cent, the white blood cell count 12,700 and the blood type O. The chest film showed calcified hilar and parenchymal scars. There was no active pulmonary tuberculosis. Sigmoidoscopy revealed minimal proctitis and internal hemorrhoids. The patient responded well to local treatment.

On May 19 the patient was readmitted to the hospital because of a recurrence of the cutaneous lesions on the sites previously affected. On entrance the hemoglobin was 100 per cent and the white blood cells numbered 8,100. On July 2 he received a single injection of 30 million killed typhoid bacilli. On the following day he was started on sulfathiazole and sodium bicarbonate therapy. After three doses of 1 Gm of the sulfathiazole in forty-eight hours chilliness, malaise, dizziness and loss of appetite occurred. The sulfathiazole was stopped immediately, though it was felt that all the symptoms were due to the intravenous injection of killed typhoid bacilli.

Twenty-six days later (July 31) the patient was again started on sulfathiazole 1 Gm with sodium bicarbonate 0.6 Gm four times a day. Concomitantly an intravenous injection of 30 million killed typhoid bacilli was given. On the first day the patient had an emesis with chills and muscular pains followed by fever for six days. During this period he received 15 Gm of sulfathiazole. At first it was believed that the typhoid vaccine was the cause of these symptoms, but the duration of the febrile response was so long that sulfathiazole had to be considered its cause.

On September 9 the patient was readmitted with a recurrence of his original dermatitis. On admission the white blood cell count was 10,500 and the hemoglobin content was 95 per cent. The fasting blood sugar was 84 mg per hundred cubic centimeters. The urine was normal. Scrapings from the skin of the axillas, groin and ears grew *Monilia albicans* on cornmeal agar. A skin test with oidiomycin 0.1 cc of 1:100 was positive in twenty-four and forty-eight hours. On the basis of these findings and the chronicity of the dermatitis, a diagnosis of moniliasis was made.

On Feb 9, 1943 the patient was readmitted to the hospital for the fifth time. He now complained of the loss of 5 pounds (2.3 Kg), diarrhea and his original dermatitis. The skin test with oidiomycin 0.1 cc of a 1:100 dilution was again positive. It was felt that the patient had moniliasis of the gastrointestinal tract as well as of the epidermis, so he was placed on succinylsulfathiazole 3 Gm every six hours. After taking 15 Gm of the drug the patient felt flushed. When he had taken an additional 3 Gm there was a chill followed by nausea and vomiting. Food and all medication were refused for twenty-four hours because of stupor. A blood sulfathiazole determination⁶ was too low to be read. On the fifth day following the administration of the drug the patient again willingly took his food and medication. There were no further complaints or febrile responses until ten days later (February 27), when following the injection of 20 million killed typhoid bacilli the temperature rose to 100 F. On the following day headache, dizziness and nausea occurred. On the next day, seventy-two hours before his death, he complained of a sore throat, fever and difficulty in swallowing. He refused his

food bath and succinylsulfathiazole, of which he had taken 159 Gm. A blood sulfathiazole determination⁶ taken at this time was again too low to be read. Physical examination showed that the patient was seriously ill with a temperature of 104.5 F, a pulse rate of 120 and a respiratory rate of 20. The skin was dry and noncyanotic. There was some swelling of the right side of the neck. The throat was bright red with a few small superficial ulcerations. There was uvular and pharyngeal edema. In twelve hours the temperature was 105 F, pulse rate 120 and respiratory rate 28. The edema of the throat had increased so much that it became difficult for the patient to breathe or even swallow water. In the mouth and throat appeared a thick gray tenacious mucoid material which added to the patient's discomfort. An epinephrine spray (1:100) to the throat and aspiration of the mucus from the mouth and throat gave a minimal amount of comfort. Repeated blood counts revealed rapidly developing acute agranulocytosis.

The patient was given a total of 1,250 cc of fresh citrated whole blood by transfusion over a period of three days. At the same time he received a daily intramuscular injection of 5 cc of liver extract. Pentnucleotide was administered in the following schedule: first day one injection of 10 cc, second day three injections of 10 cc each, third day four injections of 10 cc each. The oxygen tent was tried but was discontinued after one hour because the patient could not tolerate it. He also received daily 2,000 cc of isotonic solution of sodium chloride intravenously. Frequent warm saline mouth and throat irrigations were found to be helpful in easing the patient's general discomfort.

On the last evening the temperature was 106 F, the pulse rate 130 and the respiratory rate 30. Purpura and Cheyne-Stokes respiration developed. At 2:30 a.m. on March 4 the patient had a two minute convulsive seizure followed by cessation of respiration. Permission for autopsy was not secured.

COMMENT

Acute agranulocytosis was fatal to a youth who had received a total of 159 Gm of succinylsulfathiazole over a period of seventeen days. The patient had demonstrated reactions on two previous occasions while taking sulfathiazole and concomitantly receiving injections of killed typhoid bacilli. Though the first episode of fever might have been due to the injection of killed typhoid bacilli, the second febrile reaction was undoubtedly due to sulfathiazole. On the second day following the administration of succinylsulfathiazole a fever developed which persisted for four days. As succinylsulfathiazole is partially hydrolyzed to sulfathiazole,⁷ this febrile response no doubt was due to a sensitization to sulfathiazole, which sensitization manifested itself during the second course of administration of the drug. However, with continued administration of succinylsulfathiazole the temperature, pulse, respiratory rate and white blood cell count became normal, so it was believed that his intolerance to the drug had ceased. For eight days the patient was asymptomatic with a normal temperature and white blood cell count. His final febrile response began with the injection of killed typhoid bacilli. Acute agranulocytosis began when he had taken 159 Gm of succinylsulfathiazole and continued to termination in spite of treatment which had cured attacks of acute agranulocytosis in rats fed succinylsulfathiazole.⁸ Sensitivity has been shown to be present not only when there has been an interruption in the course of medication⁹ but also when there has been a prolonged administration of large doses of the drug.¹⁰ Both of these conditions were present in this case.

INSUFFICIENCY OF ADRENAL CORTEX COMPLICATED BY HYPERTHYROIDISM

GEORGE A. PERERA, M.D. AND DONALD D. PARKER, M.D.
NEW YORK

The physiologic relationships of the thyroid and adrenal glands, studies of which were initiated by Marine and Baumann¹ and by Davis and Hastings² have been reviewed by Lerman³. There is considerable evidence that patients with hypofunction of the adrenal cortex may be thrown into a crisis by administration of thyroid⁴ that thyroxine produces enlargement of the adrenal cortex and that other and often antagonistic correlations exist between these endocrine organs.

The clinical association of hyperthyroidism and insufficiency of the adrenal cortex has been noted but rarely. With the possible exception of 1 or 3 cases reviewed by Etienne and Richard⁵ and a more probable example described by Plé and Fabregat,⁶ we have been unable to find any references to the proved coexistence of these two diseases. Three cases have been described with a previous history of thyrotoxicosis and the subsequent development of Addison's disease⁷ and 5 others have been reported with the clinical picture of a toxic goiter in which the diagnosis of hypoadrenalism was also made but with little justification and no confirmatory evidence⁸.

Because of the physiologic antagonisms as well as the rare clinical association it becomes of interest to report a case in which hyperthyroidism and hypoadrenalism were simultaneously present.

FIRST ADMISSION

History.—M. G., an unmarried Irish woman aged 26, entered the Presbyterian Hospital in October 1940 complaining chiefly of nausea, vomiting, weakness and loss of weight for nearly two years. Her father and mother both died of cancer of the gastrointestinal tract. Three brothers and one sister were living and in good health. There was no recognized exposure to tuberculosis or family history of thyroid disease. Bilateral ovarian cysts were removed in 1937 without subsequent disturbance of the menstrual function. Otherwise she had always been well.

Two years before admission she began to experience nausea after meals and decreased her food intake. She also had excessive flatulence and belching with an occasional dull midepigastric pain. She lost weight and strength progressively, her normal weight of 125 pounds (56.7 Kg.) falling to 90 pounds (41 Kg.). Six months before entry weakness was so pronounced that she was virtually confined to bed and almost fainted whenever she got up. The systolic blood pressure then was reported to be 65 mm. of mercury. For four months there had been increasing dirty yellow pigmentation of the face and extremities without any exposure to direct sunlight. Purpura was discovered by her physician about this time, although she had no urinary complaints. Six weeks before admission cough and pain developed in the right anterior part of the chest. She was presently admitted to another hospital where after three

days of vomiting she went into profound collapse, with unconsciousness, high fever and hypotension so extreme that the blood pressure could not be obtained. Vigorous therapy with adrenal cortex extract and infusions of saline solution and dextrose led to rapid improvement. Transfer to the Presbyterian Hospital was arranged for further observation.

Physical Examination—On admission the temperature was 99 F, pulse rate 100, respiratory rate 20 a minute and the blood pressure 95/65. She was fairly well developed but poorly nourished and appeared tired and chronically ill. There was no dyspnea, orthopnea, pallor, cyanosis, jaundice or edema. The skin of the head, neck and extremities showed moderate brown pigmentation, the mucous membranes of the mouth were not pigmented. The eyes, ears, nose and throat were normal. There was no generalized enlargement of the lymph nodes. The thyroid gland was easily palpable but did not appear enlarged. The lungs were resonant, a few fine rales were heard in the fifth right intercostal space posteriorly. The heart was not enlarged and had a regular rhythm; no murmurs were heard. The abdomen was soft and nontender; the liver, spleen and kidneys were not felt. Pelvic and rectal examinations gave negative results. The deep tendon reflexes were equal and active.

Patient's course during second admission to the hospital

Laboratory Data—Urinalysis showed a specific gravity of 1.017 and no dextrose, albumin or bile; the sediment contained occasional leukocytes. The red blood cell count was 4,810,000 per cubic millimeter, hemoglobin concentration 13.4 Gm per hundred cubic centimeters, and the white blood cell count 7,900 per cubic millimeter, with a differential count of neutrophils 55 per cent, lymphocytes 42 per cent, monocytes 2 per cent and eosinophils 1 per cent. The blood Kline test was negative. The erythrocyte sedimentation rate was 66 mm in the first hour. The basal metabolic rate was plus 19 per cent. Chemical analysis of the blood serum gave the following values per hundred cubic centimeters: protein 7.2 Gm, albumin 4.4 Gm, globulin 2.8 Gm, nonprotein nitrogen 26 mg, calcium 11.4 mg and cholesterol 197 mg. The fasting blood sugar was 75 mg per hundred cubic centimeters. The serum sodium measured 138.3 milliequivalents per liter and the serum potassium 4.4 milliequivalents. X-ray examination of the lungs showed peribronchial thickening in the left first interspace interpreted as healed or inactive tuberculosis and an irregular, sharply demarcated area of increased density in the lower part of the right upper lobe thought to represent an active tuberculous process. Films of the urinary tract demonstrated flecks of calcium over the upper poles of the kidneys in the position of the adrenals, and a few small flecks of calcium density projected through the right kidney shadow. A film of the heart taken at 2 meters showed it to be of normal size and configuration. Roentgenograms of the skull were not abnormal. Fasting gastric contents concentrated and then injected into a guinea pig did not produce tuberculosis in the test animal.

Course—The temperature ranged between 98.6 and 100 F. After three days on a regular diet without added salt and without injections of adrenal cortex extract she became very weak and began to vomit. The blood pressure then was 86/50, and the serum sodium concentration had fallen to 133 milliequivalents per liter. The injection of desoxycorticosterone acetate combined with intravenous infusions of saline and dextrose produced prompt and striking improvement in her condition, and the insufficiency of the adrenal cortex was thereafter well controlled by daily subcutaneous injections of desoxycorticosterone acetate plus the oral administration of enteric coated sodium chloride tablets. Because of the elevated basal metabolic rate (plus 19 per cent, plus 20 per cent) and gross twitchings of the arms and legs, the possibility of hyperthyroidism was considered. After ten days' treatment with sodium iodide (10 drops daily) the basal metabolic rate was plus 15 per cent and no subjective change was noted. She had no fine tremor and no objective signs of hyperthyroidism were observed. Repeated films of the chest showed no significant change in the lesion of the right upper lobe. After nine weeks she was transferred to a sanatorium.

SECOND ADMISSION

History—She remained in the sanatorium for a year. Tubercle bacilli were found in the sputum occasionally and were also present in the urine. She entered the Presbyterian Hospital again in January 1942 for reappraisal, feeling much improved over her state on the previous admission and without specific complaints. She had continued to take desoxycorticosterone acetate. Her appetite was excellent, although at times she vomited undigested food. The twitching and nervousness were much less than before.

Physical Examination—The arterial blood pressure was 108/60. She was well developed but rather thin, did not appear ill and was very restless. Pigmentation of the skin was not striking, but there were now several small areas of brown pigment on the right side of the tongue and on the buccal mucous membrane. There was slight symmetrical and diffuse enlargement of the thyroid gland. The eyes were bright and somewhat prominent, with a definite stare; there was some lid lag on downward gaze. Convergence was normal. The palms were warm and moist. There was an inconstant fine tremor of the outstretched hands. Resonance was diminished in the right interscapular region, but no rales were heard. The heart was normal. The abdomen was normal. The deep tendon reflexes were equal and active.

Laboratory Data—Urinalysis on admission showed a specific gravity of 1.019 and no dextrose, albumin or bile; the sediment contained 5 to 8 white blood cells per high power field (centrifuged specimen). A specimen of urine obtained by catheterization on January 10 showed albumin 1 plus; the sediment was loaded with white blood cells in clumps. Frequent urinalyses thereafter on routine specimens and on those secured by catheterization showed usually albumin 1 plus (although occasionally none was found) and white blood cells in the sediment varying from 5 to 50 per high power field. The red blood cell count was 3,970,000 per cubic millimeter, the hemoglobin concentration 12.3 Gm per hundred cubic centimeters and the white blood cell count 8,250, with a normal differential count. The erythrocyte sedimentation rate was 38 mm in the first hour. The guaiac test on the stool was negative. The blood Kline reaction was negative. Chemical examination of the blood serum on January 9 gave the following results: protein 6.2 Gm, albumin 3.7 Gm and globulin 2.5 Gm per hundred cubic centimeters and sodium 139.8 milliequivalents per liter. The blood nonprotein nitrogen was 30 mg and the fasting blood sugar 99 mg per hundred cubic centimeters. Roentgenograms of the chest showed little change from the previous admission. Films of the upper part of the abdomen showed the calcification in the region of the adrenals and the right kidney to be unchanged. Culture of the urine yielded *Staphylococcus albus*. Three twenty-four hour collections of urine on successive days were centrifuged separately; in two of the three specimens acid fast bacilli were demonstrated. A healthy guinea pig injected with a sample of the sediment from a twenty-four hour collection of urine failed to develop tuberculosis.

9 The desoxycorticosterone acetate used in the treatment of this patient was supplied by Dr. R. D. Sharner of Roche Organon Inc., Nutley, N. J.

Course.—Five days after admission bilateral ureteral catheterization was done; no acid fast bacilli were found in the sediment of the urine obtained from either kidney. Following this procedure pain in the lower part of the abdomen, nausea and vomiting developed. The next day her temperature rose to 102.6 F. Because of the possibility that an Addisonian crisis might be impending, she was treated with an extra injection of 7 mg of desoxycorticosterone acetate in intravenous infusion of 1,000 cc of 5 per cent dextrose in 0.85 per cent saline solution and the oral administration of 1 cc of compound solution of iodine and 2 Gm of salutaridin with prompt subsidence of fever and disappearance of the symptoms. In the ten days after this single dose of iodine her basal metabolic rate fell from plus 31 per cent to plus 3 per cent and the serum cholesterol rose from 138 mg to 182 mg per hundred cubic centimeters. After three weeks these values had returned to their former levels. She now received a dose of 1 cc of compound solution of iodine daily for ten days but no improvement in the clinical signs of hyperthyroidism was observed and the basal metabolic rate and serum cholesterol concentration failed to change toward the normal levels as they had before. In the face of definite clinical and laboratory evidence of thyroid overactivity treatment to diminish thyroid function was indicated. Roentgen therapy was considered to be preferable to partial thyroidectomy as the complicating insufficiency of the adrenal cortex materially increased the hazards incident to surgery. Accordingly she received a course of eight x-ray treatments to the anterior portion of the neck over the thyroid gland at the rate of 100 roentgens a treatment (150 kilovolts, 4 milliamperes, tube-skin distance 16 inches, filter 3 mm aluminum). The dosage at the final treatment was double that of the others to make a total of 900 roentgens. At the end of the course of roentgen therapy she was unimproved but three weeks later there had occurred striking diminution in tremor, nervousness and stare and the basal metabolic rate was then plus 3 per cent. Two months after treatment was completed clinical improvement was even more striking; the basal metabolic rate was minus 24 per cent and she had gained 13 pounds (6 kg).

Throughout her hospital stay the insufficiency of the adrenal cortex was controlled by the daily subcutaneous injection of 4 mg of desoxycorticosterone acetate and the oral administration of 3 Gm of sodium chloride in enteric coated tablets. The arterial blood pressure and the serum sodium concentration remained at all times within normal limits. An x-ray film of the chest made on June 12 showed no appreciable change in the pulmonary lesion during her hospital stay. When she was allowed out of bed several weeks before discharge she complained of lumbar backache. Careful x-ray studies of the spine failed to demonstrate any lesions suspected of being tuberculous, and since the pain subsided spontaneously a complicating Pott's disease seemed unlikely. After five months in the Presbyterian Hospital she was discharged to return to the sanatorium for further care of the pulmonary tuberculosis.

COMMENT

There was no doubt that this patient had Addison's disease probably due to tuberculosis. The weakness, gastrointestinal symptoms, hypotension, pigmentation, calcification in the adrenal areas, systemic reaction and fall in the concentration of sodium in the serum following the withdrawal of salt from the diet were characteristic. Furthermore the subsequent dramatic response to therapy with desoxycorticosterone acetate and sodium chloride substantiated the diagnosis of insufficiency of the adrenal cortex with certainty.

At first the added presence of hyperthyroidism was merely suspected. However the appearance on the second admission of a diffusely enlarged thyroid, nervousness, stare and lid lag, tremor and hot moist skin together with an elevated basal metabolic rate on repeated determinations and a cholesterol level below normal made the clinical picture complete. Added confirmations were the rapid response of the basal metabolic rate and cholesterol after a single dose of iodine and the complete disappearance of all clinical and laboratory manifestations of hyperthyroidism following roentgen therapy.

It is of interest that this patient with established hyperthyroidism and hypoadrenalism, was able to withstand the

possible consequences of these combined disorders. It is of particular interest that hypoglycemic reactions, which might be anticipated on theoretical grounds did not appear. A prominent feature of her course was the subjective improvement in strength and sense of well being that followed irradiation of the thyroid, almost as pronounced as the clinical response after therapy had been instituted to alleviate the adrenal insufficiency induced by the withdrawal of salt.

A SERIOUS COMPLICATION OF CAUDAL ANESTHESIA

MURICE J. SMALL, M.D., PARSONS W. VA.

Because of the widespread interest and enthusiasm now being shown in caudal anesthesia for obstetrics this case is reported as a warning of its most serious complication, namely high spinal anesthesia even though a technique was used which was designed expressly to avoid this complication.

A secundigravida aged 23 whose previous medical and obstetric history was noncontributory except for a syphilitic infection acquired five years previously but adequately treated and with negative serologic and spinal fluid findings at present was admitted in active labor with the cervix three fingerbreadths dilated and the head in midpelvis the presentation being left anterior oblique. The membranes were intact. Blood pressure was 120/80. The general medical examination revealed no abnormalities. Caudal anesthesia was begun immediately the technique recommended by Hingson and Edwards¹ being used with one modification designed to minimize the danger of depositing the metycaine solution in the subarachnoid space. This procedure was devised at the obstetric division of the Sinai Hospital, Baltimore, and it utilizes the ordinary intravenous drip arrangement for a slow continuous flow of anesthetic solution instead of the injection of large quantities of solution at intervals. It is the contention of the originators of this modification that when the bottle containing the anesthetic solution is placed about 4 or 5 feet above the level of the patient the rate of flow of the solution will be between 60 and 100 drops per minute if the needle is in the caudal space but 150 drops or more a minute if it is in the subarachnoid space. They maintain further that a test dose of 8 cc injected as recommended by Hingson and Edwards¹ if it is in the subarachnoid space would cause serious and alarming reactions.

With this technique and a rate of flow of metycaine solution of 60 drops per minute with no pinch clamp applied to the tubing excellent caudal anesthesia was obtained in twenty minutes. My patient made rapid progress and at the end of one hour was fully dilated the membranes were ruptured and the head was just on the perineum. The patient was smiling, talkative and cooperative. Rather suddenly she appeared to become drowsy, closed her eyes, rolled her head from side to side, gave several gasps and became apneic and rapidly cyanotic. Her teeth were tightly clenched, and it was with considerable difficulty that her jaw was pried open and a mouth gag inserted. Heart sounds were rapid and barely audible. The blood pressure could not be obtained. The needle was immediately withdrawn from its supposed position in the caudal space but it was noted before doing so that the rate of flow had not accelerated; in fact it was only about 50 drops per minute. One hundred per cent oxygen was given and nikethamide injected intravenously. Artificial respiration was applied. After about three minutes the patient began to breathe and the cyanosis began to clear. The pulse became stronger and slower. The baby was extracted by forceps while resuscitative measures were being applied to the mother and was normal in every respect, crying immediately after delivery. The patient did not regain consciousness to the point at which she was cooperative for half an hour and when tested at this time she displayed a complete sensory anesthesia extending as high as the lower axillary line. There was complete motor loss of the extremities. From this point on her convalescence was exactly like that of any other patient receiving a spinal anesthetic.

From the Tucker County Hospital.

1. Edwards, W. C. and Hingson, R. A. Continuous Caudal Anesthesia in Obstetrics. *Am J Surg* 57: 759-64 (Sept.) 1942.
2. Personal instruction was given by Dr. Nathan Block, resident in obstetrics, Sinai Hospital, Baltimore.

The total amount of metycaine solution used was 90 cc over a period of about one and one-half hours. Since the rate of flow was slow throughout this procedure, even though it came from a reservoir bottle at a level of 5 feet above the patient, with unobstructed outflow, the question arises as to whether it is possible for the anesthetic solution to diffuse into the subarachnoid space, even though the needle is properly placed in the caudal canal.

This case is reported as a note of warning to the many physicians who are now employing caudal anesthesia in obstetrics. I wish to stress the importance of having a patient receiving such anesthesia move her toes frequently, since this is one of the first functions to be lost during spinal anesthesia.

Special Article

REPORT OF THE COMMITTEE ON HEALTH PROGRAMS

OF THE FORTY-FIRST ANNUAL CONFERENCE OF
THE U. S. PUBLIC HEALTH SERVICE WITH
THE STATE AND TERRITORIAL
HEALTH OFFICERS

ARTHUR I. McCORMACK, LOUISVILLE, KY, CHAIRMAN,
CHARLES F. DALTON, BURLINGTON, VT. F. J. HILL, BIS-
MARCK, N. D., PAUL J. JAKUBCH, BOSTON, CHURMAN
B. RICE, INDIANAPOLIS, JAMES R. SCOTT, SANTA FE, N. M.,
F. D. SICKLER, PORTLAND, ORE.

Since the beginning of the national defense program, the deficiencies in physical fitness of our young men and women have been one of its most outstanding and discouraging developments. We wish to emphasize that it will remain discouraging so long as we fail to develop a program which will build up and maintain physical fitness in fathers and mothers, in infants and school children in youths of both sexes, in our productive adult population and in our older people. There are no shortcuts to improving the physical fitness of a people. Improvement in this situation can be had only by a carefully planned, long-range program for the purpose of providing (1) wholesome physical environment, (2) adequate nutrition, (3) modern medical and dental services available to the people in response to their needs, (4) control of communicable disease, (5) elimination of hereditary defects, (6) sound mental hygiene and (7) effective industrial health procedures.

Many forces, social and economic as well as medical and scientific, must combine to make such a program possible. While its effect can be observed and measured only with the passing of decades, this affords us no excuse for delay in inaugurating practicable plans which would be acceptable to our people and which would secure their complete understanding and cooperation.

The medical profession of this country, including its public health agencies, has reason to be proud of its accomplishments, which are reflected in our morbidity and mortality rates. As great as these accomplishments have been, however, they afford no excuse for blindness as to our present needs or delay in starting to satisfy them. Experience in preceding years and in former wars should make physicians and health officers realize that in many of our congested industrial and war areas we are face to face with health hazards of great potentiality. These hazards bear heavily on our minds in view of our depleted resources in manpower. All states and localities have contributed many of their best qualified physicians, including health officers, engineers, nurses, technicians and educators, to the armed forces

Today, because of this shortage, too many of our health departments have little more than skeletal organizations. Further depletion of trained personnel will be disastrous. All health officers should make every effort to establish the essentiality of each key person in their departments and of each essential physician in their jurisdiction. There is no question that medical care and public health services have justified their existence in peacetime. There is even less question that they are doubly necessary in time of war, when both endemic and epidemic diseases threaten the maximal labor productivity which is demanded of all workers. The shortage of trained public health personnel makes it incumbent upon each health officer to begin planning at once to circumvent the public dangers which confront his people. Such planning may be aimed at (1) recruitment and training of professional personnel for public health work, (2) recruiting and training of lay personnel for subprofessional aides, (3) reorganizing health jurisdictions wherever it is possible to improve efficiency and equalize distribution of services so as to demand less strain on national, state and local budgets, (4) elimination of services when they are merely traditional and (5) distributing personnel in critical areas, especially in extracantonment zones and in war industrial areas, including always farming areas and food processing industries. Health officers must be confronted with and feel great responsibility about the problem of shortage of practicing physicians in many areas. The Surgeon General of the United States Public Health Service is to be congratulated on having participated with the Procurement and Assignment Service of the War Manpower Commission and the American Medical Association in developing between these agencies a joint approach to the solution of this problem. State health officers should realize that when this program is activated by the Congress with an appropriation, it will be necessary for them to follow through with official requests to the Surgeon General for personnel to be detailed to those areas where it is evident that need exists. It is feared that the problem of redistribution of physicians and dentists, already important will become increasingly so. It will probably become so acute as to require far more drastic action than has been felt necessary up to the present time.

The shortage or absence of hospital services in many jurisdictions is rapidly increasing the number of persons requiring home nursing care. It may well be that this will make it necessary for state and local health officers to consider the extension of old and the establishment of new bedside or visiting nursing services in many communities. The shortage of registered nurses is developing as rapidly as that of physicians, and a visiting nursing service can frequently be handled during such an emergency most economically if the visiting nursing work is a part of the regular public health program and under the general direction of the local health officer.

We view with considerable alarm the announced plans of the armed forces to take over the physical fit outputs of the medical schools of this country in order to assure to the armed forces a continuing flow of young physicians. It is apparent that it is impossible for our people at home to be served over a very long period by the older physicians who have been kept at home. When it is realized that the portion of each graduating class which will be available for the civilian population will replace only one fourth of those who die or become incapacitated, this procedure becomes

that must receive serious attention from interested civilian and professional groups.

We urge first, that the matter of assuring adequate medical facilities, supplies and equipment for civilians be immediately surveyed, so that the people may be assured that adequate provision will be made for these needs and second, that, having in mind the necessary redistribution of population following the war, a study be inaugurated in each state and community as to the needs for (a) medical dental nursing and other professional personnel and (b) facilities for making the services of such personnel of real value to the people they will serve, these service facilities to include additions to existing hospitals, health centers, clinics and offices. In such a survey the medical dental and nursing organizations should be fully represented.

In the distribution of physicians, both now and after the war it is essential that there be agreement as to principles and procedures among the American Medical Association, the Public Health Service, the Children's Bureau and state medical and health organizations. Such an agreement can be brought about by a meeting of minds under the auspices of the Procurement and Assignment Service and the Health and Medical Committees serving in an advisory capacity to the administrators of the Federal Security Agency. It is the considered judgment of the State and Territorial Health Authorities that adequate scientific medical care and health protection for all the people is a necessity. With statesmanlike leadership on the part of those who represent the people whose needs are involved, and the professions who are the only ones that can supply these needs, the whole suggestion of regimentation or socialization of medicine can and should be definitely and completely placed in the limbo of utopian and impracticable schemes. The freedom of the American people to choose their own physicians should be safeguarded as one of the essentials of free life.

During the present war emergency, in view of the increasing shortage of physicians, dentists and nurses in the important farming and industrial areas we approve the principle that the location of physicians within a given governmental unit should be the initial responsibility of the county or township, under the leadership of the county medical society and the local health officer. When these cannot solve their local problem it should be referred to the state. The state medical association, the State Procurement and Assignment Service and the state health organization should make by joint action every possible endeavor to provide for the necessary relocation. In instances in which this is impossible and we anticipate that there will be an increasing number of them, necessary legislation should be sought so that the states can call on the Public Health Service for such federal assistance as may be found imperative. Sometimes the solution will be found by so increasing facilities that they will invite the relocation of physicians. In other instances it will be necessary to provide temporary financial assistance to cover the expenses of the removal and maintenance of the physician, dentist or nurse until he or she becomes self sustaining. In some critical sections, over varying periods of time a considerable proportion of all the expenses of medical and health care will necessarily have to be borne by the federal government. In certain other instances during the emergency, and we trust they will be rare, the whole medical care and public health program will have to be rendered by officers of the service during a long enough period, with a sufficiently con-

structive plan, to enable the population of such localities to resume control of their own health and medical personnel under traditional standards. All investigations and all plans should be made by the Procurement and Assignment Service of the War Manpower Commission, the Public Health Service and the Children's Bureau, representing the federal government, and by local state and national medical organizations, representing the profession, and by county and state health organizations, representing the people.

We wish especially to emphasize the importance of an intensified program for the control of tuberculosis. The plan of providing for custodial care in sanatoriums of infectious cases requiring quarantine to prevent the spread of the disease should be continued. It is of the utmost importance that hospitals for the care of early cases of tuberculosis be provided wherever they are necessary. Confronted by the present demand for manpower such hospitals, with their necessary personnel, would mean that thousands of our young people can be restored to economic usefulness by prompt treatment which we cannot afford to neglect. In this connection, both the medical profession and the public should bear in mind that procedures for the finding of early minimal cases have been so simplified and perfected and the effectiveness of collapse therapy and other surgical procedures have been so successfully improved that the average treatment period in tuberculosis hospitals has been reduced from approximately two years in 1935 to six months or less at the present time.

Many public and private health services are limited because of shortage of professional personnel. The need for some of these services can be reduced through health education of the people in urban and farm homes and within industrial and war plants. Health education the purpose of which is to secure the participation of an informed and participating public becomes, therefore, the most realistic approach for fulfilling the needs of our people. The impelling motive for sustained health—patriotism, winning the war, sufficient income for self support, increased usefulness and productivity—are present now as never before, and this unusual necessity for and desirability of health education should be planned and carried on intensively at the local level. It must reach every one in the community, from the poorest to the richest. It must enlist the maximal understanding participation of the individuals who compose a community.

To be successful in health education, more attention should be given

- 1 To the employment of personnel skilled in educational technique and informed of the facts of preventive medicine. Such personnel in local health departments can be secured because personnel capable of performing this task can be found among those not essential to the military forces.
- 2 To the provision of local health department budgets for the purchase of health education materials.
- 3 To the integration of health education with the whole plan of public education, through those responsible for primary and higher education.

As programs advance, the need for trained health educators to give leadership in this field will become acute. Health officials should anticipate this need by providing training now to possible leaders.

The paramount importance of a local, state and national nutrition program has been definitely demonstrated. With twenty federal agencies having inchoate and duplicating responsibilities for a share in the devel-

opment of this program, it is recommended that the primary responsibility for its development be placed in the Department of Agriculture. There are already a farm agent and a home economic expert in almost every county. Under the existing confusion at the federal level, they are compelled to spend so much of their time conferring with one another and somebody else that the results of the really great knowledge they have too rarely gets into the pots and pans or on the tables or in the mouths of the people. All state health departments should have those specially qualified in the medical aspect of this problem to consult with and sometimes initiate out of their routine those who should be made solely responsible for an adequate feeding program for the nation. We have an abundance of food. We can multiply this abundance indefinitely, but nothing will be accomplished unless this food is distributed so that the people have access to it and are taught how to select, cook and serve those things necessary for the preservation of healthy life.

The war has brought into bold relief the paramount importance of industrial hygiene. In the development of a health program for each state, we recommend that careful consideration should be given to the following suggestions:

The Industrial Hygiene Bureau should survey and evaluate industrial health hazards in all plants.

Potential exposures to toxic materials should be analyzed quantitatively to determine actual risk to the health of workers.

Engineering services should be extended to all plants having hazards in order to secure control.

Physicians should be stimulated to report all occupational diseases in order that investigation of the working environment may be made and corrective measures taken.

The bureau should sponsor more and better plant medical departments and augmented nursing service within industry.

The bureau should make available, through cooperation with other agencies, undergraduate and postgraduate study of industrial medicine.

It should work in the closest harmony and spirit of cooperation with the committees on industrial health of the national, state and county medical societies.

It should study occupational disease incidence and medical absenteeism recording and reporting and be able to make recommendations to industrial management.

The bureau should be available at all times for consultative service to private physicians on occupational diseases.

It should sponsor industrial programs on nutrition, venereal disease, dental services and the rehabilitation of sick or injured workmen.

Special plant studies should be made on sanitation, illumination, heat and humidity, noise, shock and other causes of fatigue and recommendations made to management.

A continuous and never ending educational program should be inaugurated to labor, to management and to the public to correct bad health, preserve good health and maintain industrial production, happiness and good will.

From the address of Dr. G. W. Cox, the distinguished state health officer of Texas, on Environmental Sanitation, we make the following additions to the public health program:

Since this nation will probably be confronted with a serious postwar unemployment and health problem, it appears most highly desirable that we now plan a definite health program along environmental lines so fundamentally sound and attractive that it will be acceptable to individuals, communities, states and the nation as a whole. Therefore, in conclusion, the writer would like to recommend that plans and estimates be prepared now which can be utilized the moment labor supply

becomes available and before the health problems become acute. These plans and estimates should cover at least in part the following projects:

1 Local health centers with laboratory and equipment to house local health personnel so as to enable sanitation forces to function at their maximum efficiency.

2 Plans for water supplies and treatment where needed.

3 Sewerage system and treatment works where needed.

4 Municipal or cooperative abattoirs.

5 Municipal or cooperative oyster shucking and shellfish picking establishments.

6 Municipal or cooperative canning or food processing plants.

7 The recruitment and training of more sanitation personnel to carry forward sanitary work not only at home but in our sister republics to the south and in occupied countries (as a matter of fact, on a worldwide basis).

8 The planning of drainage systems where such drainage will minimize the mosquito borne disease problem.

9 The planning of a mutual aid program in rodent control in rat stoppage of buildings.

10 The planning of a cooperative program on garbage disposal.

11 The planning for the elimination of slum areas and making available adequate housing for the population.

12 The planning of a program which will provide adequate lighting, heating and ventilation facilities in public buildings but more especially in our schools.

13 An advisory program that would be helpful to industries in the elimination of industrial hazards.

14 Promulgation of plans which will insure our farm population safe living conditions patterned somewhat after the Farm Security Administration program which provided aid in the correction of farm water supplies, waste disposal system, screening and the like.

15 Setting up short training schools for food handlers, water and sewage plant operators as well as swimming pool operators, operators of food processing plants such as pasteurization plants and hygienists for industrial plants.

16 The initiation of immediate steps toward securing an appropriation to the Public Health Service of necessary funds, in lieu of Lanham Act funds, to inaugurate and carry out a direct emergency program of community sanitation, as has already been done in the case of malaria control.

From the address of the president, Dr. Carl V. Reynolds, the state health officer of North Carolina, we recommend for the consideration of the United States Public Health Service and of each state health department the following suggestions in regard to mental health:

The incidence of mental illness constitutes a challenge which should stimulate us to better and wider application of our increased and increasing knowledge in this field. Psychiatry has now developed to the point where manifestations of mental disturbance can be detected in their incipience and so treated as to prevent the condition from becoming permanent. We are devoting too much effort to custodial care and too little to preventive measures.

Psychosis, in its broad interpretation, is a serious menace to our economic and social order. Inmates of our mental hospitals—state, federal, local and private—aggregate more than half a million. In 1940 first admissions to these hospitals totaled upward of 100,000 and these admissions are increasing year by year.

Our immediate approach to the problem should be to treat, first, patients without psychoses, mental deficiency, alcoholism, drug addiction and personality disorders, and, then, those with psychoses, dementia paralytica and the like. Solution of the problem demands sound organization, functioning intelligently and conscientiously.

To this end, the following recommendations are offered

1 Community surveys of the prevalence of persons with psychoses, the surveys to include study of all hospital records in the community selected

2 Community psychiatric service through mental hygiene clinics, throughout the country. Early diagnosis is the key to success. The patient's environment is the rational place to start correctional measures

3 Rehabilitation of the psychotic with and without psychoses, with emphasis on those without psychoses

4 Elimination of the overlapping of agencies in the mental social and physical fields. Medical agencies should direct, with the social and physical agencies cooperating under medical direction

5 Better distribution of environmental social and medical care with individual attention to the psychotic

6 More attention to etiology and prevention and less to custodial care and cure

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

The following additional dosage form has been accepted
CIBA PHARMACEUTICAL PRODUCTS, INC., SUMMIT, N. J.
Vioform Vaginal Inserts. Each insert contains viotorm 250 mg lactic acid 25 mg boric acid 100 mg and diluent to make 2 Gm

RIBOFLAVIN (See New and Nonofficial Remedies 1942 p 559)

The following additional dosage forms have been accepted
ABBOTT LABORATORIES, NORTH CHICAGO, ILL.
Capsules Riboflavin 5 mg
Tablets Riboflavin 5 mg

POISON IVY EXTRACT (See New and Nonofficial Remedies 1942 p 20)

The following preparations have been accepted
ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Poison Ivy Extract. Packages of two 1 cc ampoules. Each cubic centimeter contains 45 mg of desiccated oily resin in a mixture of sweet almond and peanut oils.

Fresh leaves of *Rhus toxicodendron* are extracted with methanol. The solvent is removed in vacuo. The residue is dissolved in isopentane and decolorized by agitation with magnesium trisilicate. The solvent is removed in vacuo and the residue is dissolved in a sterile mixture of sweet almond and peanut oils containing chlorobutanol so that the finished solution contains 45 mg of the residue per cubic centimeter and 0.5 per cent W/V chlorobutanol.

PITMAN-MOORE COMPANY, INDIANAPOLIS

Poison Ivy Extract with Sterile Diluent. 1 cc vial marketed in a package also containing three 0.9 cc vials of sterile diluent consisting of a sterile isotonic salt solution containing procaine hydrochloride 0.5 per cent and chlorobutanol 0.4 per cent.

Fresh leaves of *Rhus toxicodendron* dried at temperatures not exceeding 60°C and sieved to remove stems and leaf midribs are macerated with absolute ethyl alcohol, using 20 cc of alcohol for each gram of dried leaves. The extract is filtered through paper then diluted to five times its original volume by adding absolute ethyl alcohol.

TETANUS TOXOID (See THE JOURNAL, June 12, 1943, p 441)

The following dosage form has been accepted
E. R. SQUIBB & SONS, NEW YORK

Tetanus Toxoid. 1 cc, 3 cc and 30 cc rubber diaphragm capped vials.

DIGITALIS (See New and Nonofficial Remedies, 1942, p 265)

The following additional dosage form has been accepted
SHARP & DOHME INC., PHILADELPHIA
Tablets Digitalis 0.1 Gm (1½ grains) (1 U S P unit)

SODIUM MORRHUATE (See New and Nonofficial Remedies 1942 p 290)

The following additional dosage form has been accepted
BURROUGHS WELLCOME & CO., INC., NEW YORK
Hypoloid Sodium Morrhuate Injection 5% 25 cc rubber capped bottle. Each cubic centimeter contains sodium morrhuate 0.05 Gm and 0.5 per cent of phenol as a preservative.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies 1942 p 555)

The following additional dosage form has been accepted
DRUG PRODUCTS COMPANY, INC., LONG ISLAND CITY, N. Y.
Pulvoids Thiamine Hydrochloride 3 mg

CAFFEINE AND SODIUM BENZOATE (See New and Nonofficial Remedies 1942 p 294)

The following dosage forms have been accepted
BURROUGHS WELLCOME & CO., INC., NEW YORK
Hypoloid Caffeine and Sodium Benzoate Injection 0.5 Gm (7½ grains) in 2 cc
Hypoloid Caffeine and Sodium Benzoate Injection 0.25 Gm (3¾ grains) in 1 cc

THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO
Sterilized Solution Caffeine with Sodium Benzoate 25% 15 cc rubber stoppered vials. Each cubic centimeter contains 0.25 Gm (386 grains) caffeine with sodium benzoate, chlorobutanol 0.5 per cent added as a preservative.

Council on Foods and Nutrition

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.
OFFICE OF THE COUNCIL.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p 156)

Nestle's Milk Products Inc. New York

DEXTROGEN, whole cow's milk evaporated and modified by the addition of dextrins and maltose, contains whole milk solids, dextrins and maltose disodium phosphate and ferric ammonium citrate.

Analysis (submitted by manufacturer)—Water 68.6% ash 1.2% butter fat 6.3% protein (N × 6.38) 5.5% total carbohydrates (by difference) 18.4% calcium 0.2% phosphorus 0.2% iron 0.0015%

Calories—1.34 per gram and 43.6 per avoirdupois ounce

Vitamins—The firm claims the following values per avoirdupois ounce of Dextrogen

115 U S P units of vitamin A
0.033 mg of vitamin B₁ (thiamine)
0.35 mg of vitamin C (ascorbic acid)

Mead Johnson & Company Evansville

PABENA, a Pabulum like preparation of a single grain product contains 85 per cent oatmeal malt syrup whey powder bonemeal sodium chloride and yeast.

Analysis (submitted by manufacturer)—Carbohydrate (by difference) 69.8% protein 14.0% moisture 8.0% minerals (ash) 4.8% fat (ether extract) 2.0% crude fiber 1.4% calcium 0.80% phosphorus 0.74% iron 0.03% copper 0.001%

Calories—3.5 per gram 100 per ounce

Vitamins—The firm has supplied evidence that this product furnishes 0.3 mg of thiamine per ounce.

H. J. Heinz Company Pittsburgh

HEINZ STRAINED APPLESAUCE—SUGAR ADDED

Analysis (submitted by manufacturer)—Total solids 16.2% total sugar as sucrose 12.8% reducing sugar as invert 8.9% acidity as citric 0.38% protein (N × 6.25) 0.20% fat (ether extract) 0.05% crude fiber 0.7% ash 0.2% total carbohydrates other than crude fiber (by difference) 14.7% calcium 44.0 mg per kilogram phosphorus 32.0 mg per kilogram iron 15 mg per kilogram copper 1.7 mg per kilogram.

Calories—0.5 per gram 14 per ounce.

EXPERIMENTAL SELECTIVE NECROSIS OF THE ISLANDS OF LANGERHANS

Dunn, Sheehan and McLetchie¹ have recently recorded the discovery that certain chemical substances can cause a sharply selective necrosis of the islands of Langerhans in the pancreas, with characteristic physiologic effects and symptoms. The exocrine parenchyma of the pancreas is left untouched. This remarkable effect was observed first in the course of experiments on the production of certain renal lesions by styryl-quinoline, a synthetic compound foreign to metabolism, and by alloxan, a component of the uric acid molecule.

The study of the effect of styryl-quinoline is limited to the observation that it can cause necrosis of the islands on intraperitoneal injection into rabbits. The action of alloxan on intravenous injection in rabbits has also been studied in detail. A single intravenous dose of 300 mg per kilogram in an adult rabbit in average state of health and nutrition was found quite certainly to cause extensive necrosis of the islands with characteristic symptoms.

The bodily temperature fell rapidly. The blood sugar, initially 100 to 140 mg per hundred cubic centimeters, increased considerably for one to two hours and then fell to 100, 50 or even 30 mg. As a rule death resulted in twelve to forty-eight hours with subnormal temperature and extreme hypoglycemia pointing to overproduction of insulin. In the albino rat a lesion similar to that in the rabbit has been produced by the subcutaneous injection of alloxan and by styryl-quinoline. The rabbit and the rat are the only animals mentioned in the present report.

The principal morphologic effect in the experiments on rabbits has been a typical coagulative necrosis in the islands of Langerhans and, as stated, without any

changes in the acinar tissue of the pancreas or endocrine glands elsewhere, except in some cases congestion with small hemorrhages in the adrenal cortex and the thymus, and "minor cytological changes in the thyroid." In many of the rabbits the islands of Langerhans were all affected, at least in the central part, with only a ring or a crescent of normal cells at the periphery. The kidneys showed an early tubular nephritis.

Chemical substances have been found which cause such precise changes in the pancreas as to establish that its function with respect to sugar is limited to the islands of Langerhans. To blot out the endocrine elements of the pancreas without injury to the acinar parenchyma is a most significant step in advance for the study of fundamental problems of diabetes.

How is this necrotic lesion produced? Are the cells of the islands stimulated? Can acute necrosis of the islands have any significance for human diabetes? These questions are discussed briefly by the Glasgow investigators. They suggest that the necrosis they have described may be the effect of overstimulation of the islands, the cells dying from "overstrain." The extreme terminal hypoglycemia seems to indicate that, for a time at least, the production of insulin was stimulated. This possibility at once raises the question whether eventually harmless stimulants of island function may not be found which will be of value in the treatment of certain forms or stages of human diabetes.

In human diabetes the lesion of the islands as usually seen is of a chronic, quiescent nature. The cause and mechanism of this lesion are unknown. Is it not possible that it may concern the late or final stages of a process initiated by chemical action on the islands, more or less like that induced by alloxan in rabbits and rats? Alloxan is a natural constituent of the body, it exists in uric acid. A main source of endogenous uric acid is voluntary muscle, which is also the greatest consumer of sugar. This consideration led the Glasgow investigators to ask whether alloxan or a purine which contains it may not be a natural hormone of muscle that regulates and stimulates the activity of the islands of Langerhans.

Considerations like the foregoing all indicate the need of continued and new research in various directions. On this point, the Glasgow investigators state "so far we can say nothing about the possibility of maintaining animals alive after necrosis of the islands, nor have we obtained chronic lesions by any form of prolonged treatment." The results of new studies on chemical necrosis in the islands under varying conditions in different species of animals will be awaited with great interest.

HEREDITY OF CANCER IN MAN

Students of the natural history of cancer in man were early impressed by the possibility that a hereditary factor might exist in its causation. The occurrence of numerous cancers, often of rare types, in certain families sometimes called cancer families, the similarities in type and in time of occurrence of tumors in identical or monozygotic twins, the racial peculiarities in susceptibility and resistance to some kinds of cancer and the tendency for some persons to develop more than one primary tumor, seen especially in those who had been cured of one cancer, were suggestive of hereditary influence.

Further investigation was made largely by geneticists who entered the field in the first decade of the present century. Their studies were almost entirely on laboratory animals, especially mice. Large, long range research projects, some of which are still under way, were begun by Tyzzer, Lathrop, Little, Pike, Strong and others. It is impossible to summarize adequately the results of the important studies, but a few general remarks can be made. While in mice a hereditary factor is present in many types of tumor, this factor is neither qualitatively nor quantitatively the same for all types of cancer. A genetic formula which would explain the occurrence of all cancers in animals has not been found. Furthermore, there appear to be species differences in the importance of the hereditary factor. While these studies have helped to define the problems of the role of heredity in human cancer, they have not solved them. They should, however, not be discontinued for that reason.

In contrast to the great effort devoted to the study of cancer in laboratory animals, the study of the heredity of human cancer has lagged, at least in the United States. Large scale long range investigations have not been reported here comparable to those of Waaler in Norway and Wassink in the Netherlands. The evidence which has accumulated indicates that the importance of hereditary factors is probably different for each type of human cancer, as in mice. Human tumors can be divided into three classes on the basis of our present knowledge in this respect: (1) a group in which a strong hereditary factor is unquestionably present, (2) those in which a hereditary factor is possibly but not surely important and (3) a group in which there is little or no suggestion of a hereditary factor. In the latter two groups a hereditary factor has not been demonstrated, but neither has it been excluded. Retinoblastoma and multiple neurofibromatosis are examples of the first group. All the more common forms of human cancer fall into the second and third groups. These include carcinoma of the stomach, colon, mammary gland, prostate, lung, uterus, biliary system and others.

More knowledge on the role of hereditary factors in human cancer is desirable from the point of view of

its own importance as well as for the direction of research in collateral fields. If it could be shown that a hereditary factor is not important in the causation of the major forms of human cancer as, for example, gastric cancer, then full efforts could be devoted to finding the immediate exciting causes, because only by controlling them could this form of cancer be prevented. If it should be shown, however, that a hereditary factor is important in the causation of this cancer, thought should be directed toward nullifying its action by genetic methods. Also known potential victims could be given special clinical observation to discover the early stages, just as care is now taken to discover early tuberculosis in contacts.

The uncertainty regarding hereditary factors in the major kinds of human cancer should be ended. This can be done only by the use of data based on human material. Serious consideration should be given to plans for collecting the necessary data.

IMMUNITY IN MALARIA

Malaria is probably now the prime disease problem of the world. Productive research has been greatly hampered by inability to infect lower animals with any of the human plasmodia and by the absence of a method for artificial cultivation of the parasite. Nevertheless progress has been made in elucidating certain aspects of the disease, even greater advances are foreshadowed by recent research.

Malarial infection, it has been assumed, confers a specific immunity against the infecting parasite. An infected person, even if untreated, generally tends toward recovery.¹ However, as pointed out by Coggeshall² in his recently published De Lamar lecture, the immunologic mechanism responsible for the conversion of an acute attack into the chronic form of the disease, the character and location of the various immune responses and the duration of infection and immunity are questions of considerable controversy.

Fortunately for the evolution of knowledge on the immunology of malaria, a malarial parasite since named *Plasmodium knowlesi*, was isolated from a cynomolgus monkey in Java in 1927. This parasite when inoculated into the rhesus monkey, almost invariably produces death. If antimalarial drugs are administered early in the course of the disease, however, the infection becomes chronic. Superinfection produced by the intravenous injection of large numbers of homologous parasites causes inapparent effects and the parasites are removed from the blood stream in the course of a few hours. When such highly immune monkeys are inoculated with *Plasmodium inui*, a morphologically similar but less virulent parasite, the course of the infection is similar

¹ Culbertson, James T. *Immunity Against Animal Parasites*. New York: Columbia University Press, 1941, chapter VII, p. 124.
² Coggeshall, L. T. *Immunity in Malaria*. *Medicine* 22: 87 (May) 1943.

to that which would occur in a normal previously uninfected monkey. These observations indicate a high degree of species specific immunity and apparently prove that some factor or factors other than a highly activated macrophage system must be involved in malarial immunity. Indeed it has been known since 1937 that protective antibodies can be demonstrated in the serum of rhesus monkeys with chronic P. knowlesi infections. Furthermore it has been shown that relapse in these animals is actually a process of autohyperimmunization (and hence beneficial) rather than a phenomenon wholly detrimental to the host. The evaluation of the humoral factor in malarial immunity is not yet complete, the accumulated evidence demonstrates that malarial immune serum can affect the parasite independent of fixed tissue cells and that the two immunologic mechanisms work concomitantly rather than independently.

The need for an effective biologic preparation against malaria is obvious. Unfortunately there seems little likelihood that a sufficiently broad immunity could be induced by inoculation with any single parasite, even if the technical difficulties of the preparation of such a vaccine could be mastered. Except for the unlikely possibility of the discovery of a new strain of malarial parasite with broad pathogenic immunizing complexes, there is little hope for an effective living or attenuated vaccine in malaria. The conversion of an acute P. knowlesi infection of rhesus monkeys into a chronic one by means of quinine, atabrine or immune serum and its destruction by sulfonamide drugs offers a clue to possibly more effective action. Partially effective immunity may be demonstrated after these measures for approximately six months. Animals thus treated may acquire severe infections when reinoculated but they will survive. Furthermore, the degree of immunity following the eradication of infection does not seem to depend on the previous duration of the disease. These observations tend to disprove the hypothesis that immunity to malarial infection terminates immediately on the disappearance of the infection. Furthermore, the ability of sulfonamide drugs now in current use to eradicate P. knowlesi in rhesus monkeys may have an implication in the problem of human malaria. Although thus far a sulfonamide or similar drug has not been discovered to be as efficient against human infections as they are against P. knowlesi infection in rhesus monkeys, the possibility of discovering some similarly acting chemotherapeutic drug, Coggeshall says, is not remote. If this could be found it would serve as a method of true causal prophylaxis such as is completely lacking at present.

The fact that a form of latent malaria in an experimental animal can be completely destroyed by chemotherapy, that the duration of immunity thereafter is brief and that eradication of an acute infection in its earlier stages leaves the host without immunity gives promise of the anticipated direction of fruitful research

of the future. The detection of the specific antimalarial antibodies together with the elucidation of their specific reactions provides a means whereby the different aspects of the malarial problem may be entirely reexamined. Progress in this direction is an urgent need.

Current Comment

THE HEALTH OF YOUNG WORKERS

Many boys and girls of 16 and 17 years and even younger now take full or part time jobs or work during summer vacation periods. In a survey¹ of mortality of young people of 15 to 19 years the death rate from all causes combined (except enemy action) was 35 per cent lower among white boys and 47 per cent lower among white girls in 1942 than the average rates for the preceding three year period. There are, however, some unfavorable spots in the record. The death rate for tuberculosis increased among white males from 15 to 24 years of age and more particularly from 15 to 19, while it decreased at all other ages up to 75. Among adolescent girls aged 15 to 19 the tuberculosis death rate in 1942 continued to decline. The death rate from accidents among white boys from 15 to 19 was 17 per cent higher than in the preceding years. The trend for boys and girls to enter industry is likely to increase at an ever growing rate as the war continues. The health of these young workers should be conserved. Protective laws are the primary safeguards. Boys and girls should not be allowed to work in atmospheres which contain harmful dusts, fumes and gases. Young boys may be crippled by heavy manual labor or by work for long periods in cramped positions. Furthermore, information should be spread that boys of 14 to 17 usually do not possess the required skill or stability to permit them to operate dangerous machines. It must also be realized that farming is a hazardous occupation and that many accidents result from attempting to handle animals or farm machinery without adequate strength or training. Every effort should be made to strengthen the bodies of these young workers.

LUDWIG'S ANGINA

Williams and Guralnick¹ advocate in the treatment of Ludwig's angina early radical surgical intervention, use of sulfonamide compounds, zinc peroxide dressings in the presence of anaerobes and preliminary exposure of the trachea in every case prior to operation, or tracheotomy in the presence of respiratory embarrassment. Intravenous pentothal sodium is recommended as the most satisfactory anesthetic. The mortality in a recent group of 20 cases treated by this method at the Boston City Hospital amounted to only 10 per cent, whereas the mortality in Williams and Guralnick's previous series of 31 cases was 54 per cent. In both groups a dental lesion constituted the predominant etiology.

¹ Statistical Bulletin of the Metropolitan Life Insurance Co. 24:1 (April) 1943.
¹ Williams, A. C., and Guralnick, W. C. The Diagnosis and Treatment of Ludwig's Angina. A Report of Twenty Cases. *New England J. Med.* 228:443 (April 8) 1943.

factor—the maturing lesion in 18 (90 per cent) of the latter series. Dental extractions immediately preceded the onset of symptoms in 12. The act of extraction is not so important from the standpoint of etiology as is the preexisting septic tooth or mouth from which the subsequent spread of infection arises. Bacteriologic studies in these 20 cases revealed the presence of streptococci in all and the presence of Vincent's organisms in 50 per cent. Examination was not made for the presence of the microaerophilic streptococcus described by Melency. Because of the presence of streptococci in all cases the authors felt that sulfonamides were indicated throughout the disease. However in their experience chemotherapy alone could not be relied on in these synergistic infections and was regarded by them as secondary to the early radical incision of the area. The sulfonamides were used both generally and locally. In some cases they placed 5 to 8 Gm of sulfanilamide crystals in the depth of the wound and loosely packed it with iodotorn gauze. Melency's method² of treating foul mouth and neck infections with zinc peroxide was found to be most effective in the presence of Vincent's organisms. In such cases dressings saturated with zinc peroxide frequently yielded a clean odorless wound in a very short time. The prophylactic use of zinc peroxide powder for several days prior to extraction would undoubtedly reduce the number of cases of this formidable infection.

CASTORIA

THE JOURNAL has previously commented on the Castoria incident.¹ A press release entitled 'Castoria Mystery Solved, Manufacture Is Resumed' issued June 23 by the Centaur Company Division of Sterling Drug Inc. offers the following explanation for the reactions which occurred following the use of Fletcher's Castoria.

The process of manufacturing Fletcher's Castoria starts with the aqueous extraction of senna, a crude drug. This extract is then added to sugar and other ingredients in a maturing tank for aging. A mild fermentation develops gradually, and the therapeutic values of the product are established with the oxidation of the active principles within it.

A year ago in our Rahway, N. J. plant, Castoria was made with a 20 per cent lower sugar content and it was up to standard in every respect.

In March and April 1943 to conserve sugar under wartime conditions we again used the lower sugar content. Our research now discloses that a change in the chemical characteristics of the water, harmless in itself in combination with the reduced sugar content interfered with the normal aging process. Fermentation was intensified and speeded up and this retarded normal reoxidation of the active principles. These deoxidized active principles known as anthroquinones, are known to have an irritant action upon the mucous membranes.

The changes which occurred during the aging of the March and April batches were so subtle that they escaped detection through our chemical testing procedures, indeed even after the presence of the irritant was known through its effect on persons its identification and the reason for its presence took weeks of research to determine.

Our research further established that when the deoxidized active principles are brought to their oxidized state either

naturally or artificially, their irritant action is entirely removed, and their laxating values developed.

Now that the cause of the condition has been definitely ascertained, procedures have been put into effect which will assure normal reoxidation of the therapeutically active principles.

As a further safeguard, the finished product will be subjected to added biological, as well as chemical, tests before it is offered for sale.

When Fletcher's Castoria is on sale again each bottle will bear a laboratory control number, which will relate to the manufacturer's full record of all production data and the packages will bear a green band instead of a buff one—to avoid confusion with any outstanding stock which may not have been returned.

FUTURE HOSPITAL BUILDING

In an interesting discussion of hospital building in the future, Elcock,¹ an English hospital architect, points out that hospitals have been constructed so far almost exclusively for the curative treatment of disease and injury. At least in details of construction, provision has not been made for the use of hospitals as health centers in a larger sense. In education toward healthful living and the prevention of disease, the hospital has assumed a rather secondary role. Firmly believing that hospitals should more and more become health centers on a broader scale than heretofore, Elcock urges that in hospital construction of the future special consideration be given to the provision of educative and preventive facilities in the form of ambulatory clinics, lecture halls, class rooms, swimming pools, outdoor and indoor gymnasiums and similar facilities. Undoubtedly there will be places and conditions in which such expansion of services would greatly increase the usefulness of hospitals as community or neighborhood health centers either by themselves or in cooperation and closer integration with health departments and other social institutions. To mention just one specific need, the increasing function of the general hospital as a center of education, diagnosis and treatment in cancer certainly demands thorough study in new hospital construction. In planning for postwar hospitals, the views advocated by Elcock merit attention.

NATIONAL HEALTH AND NUTRITION IN CEYLON

According to a recent report from the Society of Medical Officers of Health of Ceylon,¹ the high incidence of infant and maternal deaths in that country is associated with many other evidences of malnutrition. The main reason underlying the poor state of nutrition is economic. Together with economic improvement the report recommends that essential food requirements be met by adding milk, various grains, animal food—especially fish—and vegetables and fruits to the staple diet of rice, which must be continued. Vitamin A can be supplied by the production of shark liver oil. The ultimate aim, the report points out, should be to provide the population with optimum diets for full physical and mental development.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

PROCUREMENT OF PHYSICIANS

A revised procedure for the procurement of physicians, designed to overcome the lag in procurements caused by failure of many of the applications submitted to mature to the commissioned stage was announced by the Officer Procurement Service of the War Department on June 1. Briefly, the new procedure provides that state Procurement and Assignment chairmen will furnish new lists of 'available' physicians to district Officer Procurement Service offices, indicating which physicians have expressed preferences for army or navy duty but have failed to complete processing of applications for commissions. In states where physician procurement is permitted, solicitation of individual applications will then be undertaken by appropriate representatives of the Army, the Navy or the central Procurement and Assignment office. Names of those who, after a reasonable time, refuse or neglect to complete applications for commissions will be furnished to the state director of Selective Service for reclassification. Similar lists are to be furnished and contacts made in states where procurement of physicians is not permitted, looking toward the more active solicitation of all available physicians under 45 years of age.

BILLS OF CIVILIAN PHYSICIANS AND HOSPITALS FOR TREATMENT OF MILITARY PERSONNEL

The Army through its own facilities usually provides complete medical and hospital care for military personnel on the active list. Sometimes, however, soldiers are away from such facilities and emergencies arise when it is necessary to procure civilian medical and hospital treatment. Generally, accounts for such services at reasonable rates are proper public charges but, under the following circumstances, existing law or regulation forbids payment from public funds:

- 1 When the individual is absent from his station without proper authority or in desertion
- 2 When army or other government medical facilities (naval, United States Public Health Service, Veterans Administration, Indian, for example) are available in the vicinity
- 3 When the service covers treatment of an individual for a chronic disability or in elective operation for a condition which does not endanger the life of the individual and would not preclude travel or transfer to an army or other government hospital
- 4 When the individual is not on the active list of the Army—that is, when he is on the inactive retired list or is a member of the inactive reserve. Selectees who have passed their physical examinations and have been inducted into the Army, but are permitted to go home to arrange their personal affairs before reporting at a reception center for military duty, are listed as "enlisted reserve inactive" and are not entitled to treatment at public expense.

It is well, therefore, for a civilian physician or hospital to ascertain from the patient his exact status in determining whether bills for treatment should be submitted to the Army or to the individual. Bills for treatment of military personnel falling within any of the classifications 1 to 4 should be presented to the individual for settlement from his personal funds, bills for his treatment under other circumstances should be submitted to the Army for consideration.

Bills presented to the Army often give only the name of the patient and the total charge. It is important that bills show the individual's full name, army serial number, rank and organi-

zation, his post or station and his status (duty, furlough or leave, if on furlough or leave, the inclusive dates of the furlough or leave should be given). If this information is not stated, much time is lost in trying to identify the soldier, and settlement is delayed. The necessary information can generally be obtained from the soldier himself.

In addition to the information outlined in the preceding paragraph, bills should give the full diagnosis and should show complete itemization of charges with the exact period of the service, the number of visits or days of hospitalization and the rate of charges. Charges for extras not included in the rate for visits or for hospitalization such as x-ray service and medicines, should be itemized and entered separately with sufficient information to permit the audit required in connection with payments from public funds. All bills should be presented in triplicate. It is recommended that bills bear the following certificate signed by the physician or, in the case of a hospital, signed in the name of the hospital by the official authorized to receive and receipt for moneys, his official designation (superintendent, treasurer) to appear below his signature:

I certify that the above bill is correct and just, that payment therefor has not been received, that the services were rendered and the medicines furnished in the care and treatment of the persons named above, that they were necessary, and that the charges do not exceed those customary in this vicinity.

Unless this signed certificate appears on bills, War Department voucher forms bearing this certificate must be forwarded to claimants for signature before their accounts can be approved for payment.

The itemized certified bill in triplicate, accompanied by the request for treatment (if any) and other pertinent papers, should be forwarded to the commanding officer of the soldier's post. If the post is not known the bill should be forwarded to the commanding general of the service command within the geographic location of the place where the services were rendered, accompanied by all information possible respecting the soldier and the circumstances in the case, in order that necessary investigation may be made with a view to identification of the soldier and payment of the account.

NEW SURGEON GENERAL CONFERS WITH SERVICE COMMANDS

At a three day meeting in Washington in June Major Gen Norman T. Kirk, recently appointed Surgeon General of the Army, and other general officers discussed plans and programs for the coming year with medical officers of the various service commands, as follows: Col J. J. Reddy, Boston, First Service Command; Col C. M. Watson, New York, Second Service Command; Col T. B. Burnett, Philadelphia, Third Service Command; Col S. W. French, Atlanta, Fourth Service Command; Col E. C. Jones, Columbus, Fifth Service Command; Col Don Hildrup, Chicago, Sixth Service Command; Col Neil J. Everitt, Omaha, Seventh Service Command; Col W. I. Hart, Fort Sam Houston, Eighth Service Command; and Col Harvard Moore, Fort Douglas, Ninth Service Command. General Kirk gave a description of his recent trip to North Africa, detailing the medical problems encountered during the North African campaign.

HOSPITALS DESIGNATED FOR SPECIAL SURGICAL TREATMENT

The Adjutant General's Office Washington, D C, issued the following memorandum on May 20 Memorandum No W40 9-43 this office 6 March 1943, subject as above, is recommended and the following substituted therefor

1 It has become evident that certain diseases and injuries will require treatment of a surgical nature in which a high degree of specialization is necessary Patients received from overseas who require the specialized treatment indicated below will be classified by the general hospitals receiving them and reported to the Surgeon General for transfer to designated specialized hospitals Patients requiring such treatment and whose disability was incurred in the continental United States will be treated in the general hospital to which originally transferred unless in the opinion of the commanding officer of the hospital adequate facilities do not exist for their proper treatment in which case they will be reported to the Surgeon General for transfer to designated specialized hospitals

2 The following general hospitals have been designated for the specialized treatment indicated

(a) Chest surgery

Fitzsimons Denver
Hammond Modesto Calif
Kennedy Memphis Tenn
Walter Reed Washington D C
Brooke San Antonio Texas

(b) Maxillofacial and plastic surgery Ophthalmic surgery

Bushnell Brigham Utah
O'Reilly Springfield Mo
Valley Forge Phoenixville Pa
Walter Reed Washington D C

CAPTAIN JADOSZ AWARDED SOLDIER'S MEDAL

The United Press recently reported from General MacArthur's headquarters in Australia that Capt Frank C J Jadosz of the medical corps had been decorated with the Soldier's Medal for gallantry for rescuing wounded fliers from a plane that had crashed with a full bomb load Captain Jadosz resided in Providence, R I where he interned at St Joseph's Hospital entering active service in October 1941

THE NEED FOR MORE ARMY NURSES

Army nurses are now stationed in thirty-five bases outside the United States as well as at 537 stations in the continental United States, the War Department announced on June 1 The need for more Army nurses remains pressing Recruitment of nurses took an upward trend in the first three months of 1943 but the opening of new hospitals and an increasing number of overseas assignments are depleting the number of nurses in the reserve pool It is estimated that one out of every four nurses in the nation will be needed by some branch of the armed forces by the end of this year Courses in military orientation and physical conditioning established throughout the nation for Nurse Corps units generally require four weeks of class room application and drill ground calisthenics at the time the nurses enter the induction centers for enrollment in the corps Heading the Army Nurse Corps is Col Florence A Blanchfield, who was formally appointed superintendent of the corps on June 1 Prior to the retirement of Col Julia O Flikke as superintendent of the Army Nurse Corps she was assistant superintendent, with the rank of lieutenant colonel

COMMISSIONS FOR WOMEN PHYSICIANS

Women Physicians who are at present either members of the Women's Army Auxiliary Corps or Contract Surgeons may now secure commissions in the Medical Corps, Army of the United States They should apply to the Office of the Surgeon General Washington, D C If the application is approved after clearance by the Procurement and Assignment Service it will be forwarded to the Officer Procurement Service for further processing Members of the WAAC will then secure a release through channels from the Director Women's Army Auxiliary Corps Contract Surgeons will be similarly processed except that they will be released by the Commanding General of the Service Command by whom their contracts were effected or in the case of the Military District of Washington by the Surgeon General

DR HENDERSON APPOINTED CONSULTANT

Dr Elmer L Henderson Louisville Ky, member of the Board of Trustees of the American Medical Association has been appointed special consultant to the Secretary of War in regard to surgical problems concerning the U S Army Air Forces Dr Henderson's appointment was made at the request of Brig Gen David Grant, the air surgeon Dr Henderson will maintain his position on the staff of the Kentucky Baptist Hospital and St Joseph's Infirmary in Louisville and will go back and forth to Washington at regular intervals for conferences under the jurisdiction of the Surgeon General of the Army His appointment became effective on May 18

LENGTHEN M A C TRAINING PERIOD

Beginning with the class which reports for training on July 9, the Medical Administrative Corps Officer Candidate School at the Medical Replacement Training Center, Camp Berkeley Texas, is lengthening its training period from twelve to sixteen weeks In announcing this scheduled compliance with a War Department directive, Col George E Armstrong assistant commandant of the Camp Berkeley school said the new schedules will involve no addition of material but will merely mean a more intensive coverage of the work now included All departments of the school—training administration logistics tactics sanitation and chemical warfare—will be allotted some of the extra hours added to the curriculum

The present field work will be especially affected by the new schedules which have been submitted to the War Department training division A continuous problem in medical support will be carried out during a six day bivouac for each Camp Berkeley class and the candidates will practice choosing aid station sites evacuation routes and other medical installations in simulated battle conditions The strength of the school twelve companies will remain the same with the result that the output will be slightly decreased Over six thousand men have already received commissions as second lieutenants in the

Medical Administrative Corps from the Camp Berkeley school. Another large group was commissioned by the school at Carlisle Barracks, Pennsylvania, before the M A C school there closed this spring.

MEDICAL SECTION OF TRAINING SCHOOL DISCONTINUED

The medical section of the AAF Officer Training School at Miami Beach, Florida, has been discontinued, it was announced, early in May. The six weeks program, which was under the direction of Major Sidney Davidson, flight surgeon, was an orientation course for medical officers which also furnished technical and tactical training. There were courses in aviation medicine, treatment of gas casualties, military art, military hygiene and sanitation. The other members of the staff were Capt R. Beverly Ray, M. C., Capt Herman W. Roth, M. C., Capt Thomas J. Eaton, Sanitary Corps, Lieut Paul S. Anderson, M. C., Lieut Allen B. Crumden, M. C., Lieut Victor F. Thompson, M. A. C., Lieut Fred W. Dixon, M. C., Lieut Frank J. Pickett, M. C., Lieut Ronald J. Roemer, D. C., and Capt Irving S. Gordon, D. C.

GRADUATES AT CARLISLE AND CAMP BARKELEY

Graduation exercises were held on June 1 at the Medical Field Service School, Carlisle Barracks, Pennsylvania, for fifty-nine officers of the medical department, following completion of a course of training for particular assignments in medical battalions of a new infantry division. Of the class forty-six were members of the medical corps, twelve of the medical administrative corps and one of the dental corps. Twenty-eight members of the class had graduated previously from a basic course at the Medical Field Service School, and nine other members had previously attended special cadre training classes at Carlisle.

Physically hardened and well trained for duty with troops in the field, 268 officers of the army medical department graduated at the Field Service School at Carlisle Barracks, Pennsylvania, June 17. The physicians, dentists, veterinarians and members of the sanitary and medical administrative corps who composed this class proceeded to their new stations immediately after the ceremonies.

The seventeenth class of the Medical Administrative Corps Officer Candidate School at the Medical Replacement Training Center at Camp Berkeley, Texas, graduated on June 9. The new lieutenants who were chosen from the ranks were given special training in administration, supply, personnel, sanitation, evacuation and training. Among those commissioned were fifteen Negroes. The graduating address was given by the school commandant, Brig Gen Roy C. Hefebower.

THREE HUNDRED AMERICANS DIE IN JAPANESE PRISON CAMPS

Messages through the International Red Cross from Japan have notified the War Department of the names of more than 300 American soldiers who have died in prison camps since the fall of Bataan and Corregidor. Disease is stated in each case as cause of death. Malaria, diphtheria, dysentery and pneumonia are the major causes. Some cases of beriberi are reported. Earlier, more than 300 deaths due to battle wounds had been reported from Japanese sources. The deaths by disease are out of a total of 11,307 army personnel thus far reported as prisoners of war of Japan.

PROMOTIONS AT FORT CUSTER

The commanding officer at Fort Custer, Michigan, recently announced the following promotions of medical officers at the Station Hospital: commanding officer, Lieut Col John G. Slevin to colonel. Colonel Slevin has been commanding officer of the hospital since October 1942, Capt Allen W. Byrnes, M. C., assistant chief of the neuropsychiatric section, to major, the following first lieutenants to captains: Keith B. Appleby, William E. Nesbitt, Henry A. Hanelin, Elmer H. Tofteland, Claude M. Eberhart.

PRISONERS OF THE JAPANESE

The War Department has announced, according to the *Military Surgeon*, that Lieut Col W. Hinton Drummond and Major Eugene C. Jacobs, both of the medical corps, were held as prisoners of war by the Japanese. Lieutenant Colonel Drummond went to the Philippines from Walter Reed General Hospital in Washington in 1940 and was serving at the Sternberg General Hospital in Manila when the war broke out. Major Jacobs was serving at the headquarters of the Sixth Corps Area in Chicago in 1940 when ordered to the Philippines, where he served as post surgeon at Camp John Hay at Baguio.

Mr. and Mrs. Benison, Flint, Mich., have been notified that their son, Lieut Arthur L. Benison of the medical corps of the Army of the United States, has been located in a Japanese prison by the International Red Cross. Dr. Benison was on duty with a medical field unit on Bataan and has been carried as missing in action for more than a year. Dr. Benison graduated from the University of Michigan Medical School in 1937.

AVIATION PHYSIOLOGISTS

The eighth class of Aviation Physiologists graduated at the School of Aviation Medicine, Randolph Field, Texas, on May 29. The five weeks course treats of the effects of lowered barometric pressure, anoxia, the effect of flight on man, the operation of low pressure chambers, the use of oxygen equipment and high altitude indoctrination and classification. Among the graduates were the following physicians: Major Marco A. Gaviola, Capt Joseph Ney and Hurley L. Motley, and 1st Lieuts Edward H. Ahrens, James Goodfriend, Sidney D. Igo, Robert J. McNeil and Dennison Young.

THE BAXTER GENERAL HOSPITAL

Baxter General Hospital in Spokane, Wash., 5 miles north west from the center of the city, is located in a pine grove on a high, wedge shaped plateau of land formed by a sweeping curve of the Spokane River. The hospital is named in honor of Jedediah Hyde Baxter, Civil War surgeon, whose appointment as Surgeon General on Aug. 16, 1890 was terminated by his untimely death on December 4 of that year. Baxter General Hospital was activated on Aug. 21, 1942. Originally planned as a 1,000 bed cantonment type hospital, it was within two weeks ordered enlarged to 1,500 bed capacity. Construction began on July 7, 1942 and includes about 150 buildings. The next few months should find the hospital ready for full activities.

The commanding officer is Col A. B. McKie, U. S. Medical Corps, and the executive officer is Lieut Col Charles H. Bremhitt, Medical Corps. The staff of medical and dental officers came from all corners of the country. As of April 24 the officers thus far assigned were:

MAJORS

Edwin S. Bennett, M. C., Operations and Training Officer
Henry S. Campbell, M. C., Chief, Dermatology and Outpatient Clinic
Section
Henry B. Elkind, M. C., Chief, Neuropsychiatric Section
Wayland K. Hicks, M. C., Chief, Urology Section
Robert D. Johnson, M. C., Chief, Dental Service Branch
Nicholas E. Lacy, M. C., Chief, Eye, Ear, Nose and Throat Service Branch
John J. Loutzenheiser, M. C., Chief, Orthopedic Section
Charles H. Maulove, M. C., Chief, Laboratory Service Branch
Russell F. Miller, M. C., Chief, X-Ray Service Branch
Everett B. Muir, M. C., Chief, Eye Section
Merritt H. Stiles, M. C., Chief, Medical Service Branch
Maurice A. Walker, M. C., Chief, Surgical Service Branch

CAPTAINS

Murray M. Berger, M. C., Chief, Eye, Ear, Nose and Throat Section
Robert T. Boyd, M. C., Orthopedic Section
Maurice V. Lang, M. C., General Surgery Section
Estel B. McCollum, M. C., Septic Surgery Section
George J. McHaffey, M. C., Pathologist
George M. Pike, M. C., Chief, Officers Section
Wallace P. Sheely, M. C., General Surgery Section
Walter R. Springstun, M. C., Registrar
J. Ray Van Meter, M. C., Neuropsychiatric Section

LIEUTENANTS

Sidney S. Epstein, M. C., Ophthalmologic Surgery
Robert L. Rein, M. C., Receiving and Disposition Officer
Herman L. Rudolph, M. C., Physical Therapy Section
Elizabeth M. Beedles, A. N. C., Chief Nurse
Catherine W. Camper, A. N. C., Anesthetist
Lorene V. Stroup, A. U. S., Dietitian
Dorothy M. Eagon, A. U. S., Physical Therapy Aide

MISCELLANEOUS

CALL FOR UNUSED X-RAY EQUIPMENT

The Safety and Technical Supplies Division of the War Production Board has issued a statement calling on physicians and dentists throughout the country to release their x-ray equipment not now in use in order to provide sufficient x-ray equipment for civilian needs.

Members of the medical and dental professions going into the armed services and all others who are temporarily not using their x-ray apparatus are urged to dispose of it. Francis M. Shields, director of the Division said. The demands for this equipment by the armed forces are heavy and will necessarily increase. Moreover, production is limited by shortages of critical materials, skilled workers and other factors. It is imperative that every item of x-ray equipment should be kept at work.

Doctors and dentists who are not now using their apparatus should sell it not only as a patriotic duty but also as a matter of self interest. Because of rapid developments that are taking place, the doctor who stores his equipment when he goes to war may well find that it is obsolescent and of no use to him when he returns to civilian life and private practice. He can far better serve both his country and himself by letting some one else use it now when it is so greatly needed.

An inventory of used x-ray equipment available for sale is being compiled by the Safety and Technical Supplies Division and well over a thousand items are already registered. All owners of idle apparatus are asked to report to the Division on Form WPB 1976 giving complete data about the equipment: its condition and selling price. Some of the equipment already registered is too old or broken down to be of use. What is needed is apparatus capable of active service but now idle. Doctors, dentists, distributors, etc. looking for used equipment are in turn asked to make their needs known to the Division so that their requests may be checked against apparatus that is for sale.

Under the terms of Lamination Order L 206 issued in October 1942, Division officials explained, the sale of new x-ray equipment is registered to the armed forces and civilian purposes approved by WPB.

EXHIBIT OF AERIAL PHOTOGRAPHS
IN CHICAGO

The British Consul General Mr W. H. Gallienne and the trustees of the Museum of Science and Industry issued invitations to a private viewing of an exhibition of aerial photographs at the Museum of Science and Industry in Jackson Park, Chicago, on July 2 between 10 a. m. and 5 p. m. These much enlarged photographs had just arrived from Britain and although some of them had been on view in the offices of the combined chiefs of staff in Washington they had not been seen elsewhere in this country. They include among others photographs of the bombing of Berlin and of the Moehne and Eder dams. Officers of the Royal Air Force were present to explain and interpret the exhibition.

THE STUDENT WAR NURSING RESERVE

The first meeting of the advisory committee of the Student War Nursing Reserve set up by the Bolton-Bailey act was held on June 25 in Washington, D. C. According to an announcement by Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, under whom the war emergency project will be administered, Miss Lucille Petry and Mrs. Eugenia Spalding, both on the nursing education staff of the U. S. Public Health Service, have been appointed director and associate director respectively of the new program. Dr. Parran pointed out that the act was drafted with the cooperation of nurse training institutions, hospitals, the nursing profession and governmental agencies.

Money will be paid quarterly in advance in the amounts estimated in order to enable hospitals to carry out the provisions delegated to them by the act. Rules and regulations for post-graduate and refresher courses under the Bolton-Bailey act will be similar to those that have been in operation under the

Training for Nurses' (national defense) law. Payment to student nurses will be made through schools of nursing on the basis of the plan submitted by schools to the Surgeon General, U. S. Public Health Service, and approved by him. The law sets forth the requirements which must be incorporated in the plan. The bill passed without a dissenting vote in both the House of Representatives and the Senate, and was signed by President Roosevelt on June 15.

WARTIME GRADUATE MEDICAL
MEETINGS

An additional group of tentative programs of Wartime Graduate Medical Meetings, a preliminary list of which was given in THE JOURNAL, June 5, page 382, has now been prepared.

The suggested six hour schedule on aviation medicine is under the direction of Lieut. Col. W. Paul Holbrook. The program is to include general orientation on the flight surgeon's work and discussions of the eye, ear, nose and throat, mouth and teeth, cardiovascular system, gastrointestinal system, genitourinary system, psychiatry and skin as they relate to aviation medicine. There are to be also discussions of the general problems of high altitude physiology including anoxia, bends and exposure to cold.

Chemotherapy is under the direction of Dr. Chester S. Keefer. The program is to include the treatment of bacterial meningitis, prevention and treatment of wound infections with sulfonamides, treatment of gastrointestinal and genitourinary infections as well as respiratory infections with sulfonamides and sulfonamide toxicity and sensitization.

The national consultant on clinical dermatology is Dr. Chester A. Frazier. The subjects suggested include care of the skin and interpretation of disease problems of acute infections of the skin and problems of minor trauma and hypersensitiveness of the skin.

The program on the dysenteries is under the direction of Lieut. Col. Thomas T. Mackie. The suggested program includes discussions of classification, geographic distribution, military importance, epidemiology and control of the dysenteries and discussions of bacillary dysentery, amebiasis, other intestinal protozoal infections and helminthic dysentery.

Dr. David P. Barr is national consultant for hypertension and nephritis and diseases of the blood. The former will include discussions of the clinical manifestations, complications and management of hypertension, nephritis, glomerulonephritis, nephrosis, pyelonephritis and nephrosclerosis. Diseases of the blood will include those involving the red cells, those involving the white cells and the hemorrhagic states.

The program for physical therapy is under the direction of Dr. Frank H. Krusen. It is to include discussions of physical agents commonly employed in medical practice such as heat, electrotherapy, light and hydrotherapy. The clinical applications of physical agents with special reference to military medicine are also to be discussed.

Psychosomatic medicine is under the direction of Dr. John Romano. There is to be general orientation followed by clinical discussions of organ and system syndromes and special emphasis on the applications of psychosomatic medicine to military problems.

The program on laboratory medicine for which Dr. Roy R. Kracke will serve as national consultant is divided into six suggested six hour schedules which could be given consecutively or individually.

The program on acute respiratory disease is under the direction of Dr. Francis G. Blake. It is to include discussions of epidemiology, clinical considerations of the acute upper respiratory infections, influenza and pneumonia and the prevention of these and their complications.

The national consultants for shock, burns and plasma are Comdr. Lloyd R. Newhouse and Lieut. Col. Douglas D. Kendrick. The suggested six hour schedule consists of two hours devoted to shock, two and one-half hours devoted to burns and one and one-half hours devoted to blood derivatives.

The program on chest surgery which is under the direction of Dr. Leo Eloesser includes a considerable amount of time

devoted to the physiology of chest injuries and discussions on the prevention of infection and on the treatment of infection.

Dr. R. A. Vonderlehr is consultant for the schedule on venereal diseases. Under this program both syphilis and gonorrhea will be discussed from the standpoint of control, prophylaxis, diagnosis and treatment.

ADDITIONAL ALLOTMENT IN ILLINOIS FOR OBSTETRIC CARE TO WIVES OF SERVICE MEN

The state director of public health of Illinois, Dr. Roland R. Cross, announced on June 15 that the U. S. Children's Bureau had granted his request for an additional June allotment of \$86,000 to be used in paying physicians and hospitals for obstetric care to the wives of service men and pediatric care to their infants in case of acute illness. The demand for this service has increased greatly. In May alone the Illinois Department of Public Health authorized care for about 550 cases of infants as many as were authorized in the preceding six months. The regulations governing this project in Illinois, as approved by the state medical society, provide that the applications for this medical care should be signed both by the service man's wife and by the licensed physician of her choice and submitted to the state department of public health in advance. The necessary forms may be obtained from local health and welfare offices and Red Cross chapters or directly from the State Department of Public Health at Springfield.

PUBLIC HEALTH UNDER HITLER

Le Nouvelliste de Lyon of April 1 complains of the unnecessary difficulties encountered by expectant mothers in order to obtain special pregnancy cards. They have to waste many hours detrimental to their health, in going to distant offices, queuing and so on just for red tape formalities. The practice is contrary to the official propaganda campaign.

The *Journal officiel*, France, of April 4 carries the text of a law laying down the conditions under which the secretary of state for health will call up chemists, doctors and dentists for the "relève" (draft). Repatriated prisoners or those who on account of their age or their families are unable to comply will be granted exemption. Doctors, chemists or dentists who are liable to be called up under the "relève" will be chosen by the high council of the medical profession (Conseil supérieur de l'Ordre des médecins).

NPD, Poland, of April 6 reports from Cracow. The successful fight against typhus (flekkieber) in the Cracow district is making further progress. Mobile hot air chambers go from place to place to delouse people in the infected dwellings which have been discovered. Four emergency hospitals are ready to receive infectious cases and are able to cope effectively with the epidemic even when widespread. Leaflets, illustrated advertisements and exhibitions constantly draw the attention of the population to the dangers of typhus and the methods of meeting it.

What applies to military operations will apply all the more to the opening up and settlement of the East. This is the field of action of geomedicine, Prof. Dr. Heinz Zeiss explains in the *Zeitschrift für Geopolitik* of the science of topographic medicine (raumbezogene Medizin), which has to fulfil tasks without which the military, political, cultural and economic opening up of the East would be impossible. It deals with research into the relations as regards time and place between the development of disease and topographic features. A campaign against infectious diseases is impossible without a map, and thus it is one of the most urgent tasks to compile a reliable atlas of epidemic diseases. It will render great service to the military and civilian health services in the East. A number of examples (sweating sickness, poliomyelitis, cholera, tularaemia) show even at this early stage how close is the relationship between the topographic nature of a region and the

occurrence of epidemic diseases. It can be shown that waves of epidemic diseases come to a halt at certain definite geographic and biogeographic features. Science in turn will be able to draw conclusions regarding areas of a similar nature and thus take preventive measures. The development of the science of geomedicine thus opens wide fields of fruitful collaboration among the civilized European nations.

NDZ, Germany, of April 8 states that numerous Volksgenossen have repeatedly shown their interest in the question of how air raid protection during alerts is carried out in hospitals. The accommodation of the patients is arranged in accordance with the nature of their disease, under a decree of the Reich Air Minister quoted by the *Sirene*. Seriously ill patients must never be put on the upper floors, as it would be difficult to carry them from there to the air raid shelters. Only patients who can be easily moved or are able to walk may be put in these rooms. During air raid warnings the latter category have to go to the air raid shelters which have been set up in the basement for the hospital staff and patients who are not confined to their beds. The seriously ill confined to beds and patients who cannot be easily moved are from the outset to be put in wards which are specially protected against splinters and left there during the alert unless special arrangements have been made for these patients by order of the Reich Air Ministry. The ARP measures in hospitals are constantly being checked and improved in accordance with the latest experience.

According to *Svenska Dagbladet*, Stockholm, of April 10 the German authorities have now confiscated Trondheim Hospital and the patients have been removed to private houses which have been requisitioned from the civilian population, preferably from the opposition. The Red Cross hospital has been fitted up as a surgical department, while the medical department has been moved to Hispegaten and the epidemic department to the Craftsman's Home for the Aged. Tuberculous patients have still nowhere to go, but requisitioning for them is proceeding.

According to *Nationaltidende*, Denmark, of April 8 the diphtheria epidemic at Noeresundby is regarded as very serious. Of 40 patients, 13 have already died. The health authorities urgently request Aalborg municipality to take immediate precautions. This new diphtheria has been caused by war conditions of a hitherto unknown and serious character. The germs spread quickly, poison the patient and paralyze the heart. Mayor Jorgensen of Aalborg has agreed to summon the epidemics board on April 9 but continues to be skeptical regarding general vaccination for the children of the municipality.

The Berlin correspondent of *Svenska Dagbladet* of April 1 writes that it looks very much as if the German birth rate will be stimulated by the duty of women to work. A reader of the *Schwarze Korps* takes up this problem and accuses certain German women of preferring to have a child rather than work in a factory, as expectant mothers are exempt from the duty to register. Thus there are women who have not had any children for ten years but who are suddenly becoming pregnant. But the newspaper, which is usually very severe, does not agree with the writer. "The state expected this development. The war losses must be balanced and the population must be increased to such an extent that the conquered living space can also be filled with German life. The conception that work comes before children would cause a national catastrophe. We need children, who are as important as anything else, and this fact is quite indisputable."

"Another population problem which has become acute as a result of the war is marriage. War causes everything which is bad and rotten to decay more quickly and it is so in marriage." This statement by the newspaper is quite correct and tallies with the latest population statistics, according to which the number of divorces on the grounds of adultery has increased by 12 per cent among men and by 134 per cent among women.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 696 has been reported to the Senate a bill to amend the United States Employees Compensation Act so as to bring postmasters within the purview of that act. The Senate Committee on Education and Labor has voted to report favorably S 1130 a bill to provide for the care of children of mothers employed in war areas. H R 986 has passed the House proposing to amend Veterans Regulation No 10 so as to redefine for compensation and pension purposes the term misconduct and to limit the meaning of that term to felonious misconduct. H R 997 has passed the House to amend certain provisions of the National Defense Act of June 5 1916 by eliminating the Medical Administrative Corps in the Medical Department of the Regular Army and substituting therefor a Pharmacy Corps. H R 2536 has passed the Senate with amendments proposing to provide for the promotion or vocational rehabilitation of persons disabled in industry or otherwise. H R 2935 has been reported to the Senate with amendments a bill making appropriations for the Department of Labor the Federal Security Agency and related independent agencies for the fiscal year ending June 30 1944. The Senate Committee on Appropriations recommended that there be eliminated from the bill the proviso that no part of any appropriation made for the Children's Bureau in the bill shall be used to promulgate or carry out any instruction order or regulation relating to the care of obstetrical cases which discriminates between persons licensed under state law to practice

obstetrics. H R 2936 has passed the House authorizing an additional \$200 000 000 for expenditure under the Lanham act for the construction of schools waterworks sewers sewerage garbage and refuse disposal facilities public sanitary facilities works for the treatment and purification of water hospitals and other places for the care of the sick recreation facilities and streets and access roads.

Bills Introduced—S 1168 introduced by Senator Reynolds North Carolina provides that on and after July 1 1943 each member of the various selective service local boards each government appeal agent and each examining physician who assists in the administration of the Selective Training and Service Act shall be entitled to receive compensation for his services at the rate of \$600 per annum payable monthly. S 1250 introduced by Senator Reynolds North Carolina and H R 3021 introduced by Representative May Kentucky propose to repeal section 2 of the act approved May 17 1926 which provides for the torticure or pay of persons in the military and naval service of the United States who are absent from duty on account of the direct effects of venereal disease due to misconduct. H R 3011 introduced by Representative O'Ronski Wisconsin proposes to authorize an appropriation of \$25 000 000 for the relief of resort owners and for sending convalescing veterans to resorts at a per diem weekly or monthly rate to be agreed on by the Veterans Administration and the resort owners.

WOMAN'S AUXILIARY

Arizona

At the annual meeting of the Woman's Auxiliary to the Arizona State Medical Association in Tucson May 1 Mrs. E. M. Hayden assumed the presidency succeeding Mrs. Harlan P. Mills. Mrs. James H. Allen of Prescott was elected president elect. Mrs. Frank N. Haggard President of the Woman's Auxiliary to the American Medical Association was guest speaker at the luncheon at the home of Mrs. Samuel H. Watson. Lieutenant Colonel W. J. Kennard commanding officer of Davis-Monthan Field at Tucson talked to the assembly on 'The Flight Surgeon in the Combat Zone'.

California

War-time Medicine in the South Pacific was discussed before the Alameda County auxiliary at a recent meeting. Lieutenant Robert Dennis Lee (MC) U. S. Navy spoke on 'The Practice of Medicine Under Combat Conditions'. Lieutenant Beth Veley of the Army Nurse Corps one of the last persons to leave Bataan discussed the care of the sick and wounded at Bataan and their escape.

At the meeting of the Los Angeles Long Beach Glendale and Pasadena auxiliaries Mr. Boyd Comstock spoke on the 'Italian Reaction to Nazi Domination'. Mr. Comstock formerly assisted the Italian government in its program for the development of young Italian athletes.

A five hundred word essay contest was sponsored by the Woman's Auxiliary to the California Medical Association among California high school students on the subject 'Fight Cancer with Knowledge'.

Georgia

The first doctors aide corps organized by the auxiliary to the Fulton County Medical Society under the presidency of Mrs. Edgar H. Greene has its headquarters and the principal laboratory of the Blood Type Registry at the Academy of

Medicine 875 West Peachtree Street N. E. Atlanta. The corps is composed of doctors' wives who after completion of a series of health education and civilian defense lectures work in one of four specialized avenues of endeavor. Of the 205 eligible auxiliary members, 143 registered for the doctors aide course. At the Academy of Medicine February 3 Dr. Thomas Parran Surgeon General of the United States Public Health Service, accepted the invitation extended him by Mrs. Greene to inspect the Blood Type Registry.

Missouri

The nineteenth annual meeting of the Woman's Auxiliary to the Missouri State Medical Society was held in St. Louis in April with Mrs. Frank L. Davis president presiding. One hundred and fourteen members attended this meeting. Guest speakers were Dr. Morris Fishbein of Chicago Editor of THE JOURNAL, Dr. H. L. Kerr president of the Missouri State Medical Society and Mrs. Frank N. Haggard President of the national auxiliary. Mrs. R. C. Haynes Marshall is president for the coming year and Mrs. J. B. McCubbin Fulton is president-elect.

OFFICIAL NOTES

SUMMER HEALTH HINTS

The next three programs for the new series of broadcasts over WLS on Thursdays at 2:45 p. m. under the title 'Summer Health Hints' will be as follows:

- | | |
|---------|-------------------|
| July 8 | Insects |
| July 15 | Poison Oak or Ivy |
| July 22 | Keeping Cool |

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF INTEREST OF MORE OR LESS GENERAL INTEREST, SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Physician Needed—A resident physician aged 21 to 55 to assist in the care and treatment of patients in the Los Angeles County General Hospital in the anesthesiology service is being sought by the Los Angeles County Civil Service Commission. Applications will be accepted from graduates of an approved medical school who have completed or who are now completing a one year's internship in an approved hospital. There will be no written examination. Candidates will be rated on their professional training and experience and their aptitude and personal suitability for advanced training in the specialty of anesthesiology as evidenced by investigation and interview. Full information may be secured from the office of the Commission, Room 102, Hall of Records, Los Angeles 12 California. Applications must be received on or before Wednesday, July 14.

DELAWARE

Twenty-Five Years in State Service—On May 2 Dr Mesrop A. Harunian observed the twenty-fifth anniversary of his association with the Delaware State Hospital, Philadelphia. The state journal reported that in 1918 he was appointed assistant physician. In 1925 after serving as assistant superintendent, he was made medical director. In 1926 he became superintendent of the hospital and in 1929 director of the mental hygiene clinic and state psychiatrist and criminologist.

Society News—Dr Jacob A. Bergen, Rochester, Minn., addressed the Academy of Medicine, Wilmington, May 21, on 'The Varieties of Ulcerative Colitis: Their Relation to the Current War and Their Management'. Dr George J. Bones discussed the Kenny treatment of infantile paralysis before the New Castle County Medical Society at a meeting in Wilmington recently. Drs Charles I. Wagner and Lewis B. Flinn participated in the discussion, all are of Wilmington.

GEORGIA

Graduate Clinics Canceled—The annual postgraduate clinics sponsored by the Emory Medical Alumni Association will not be held this year. The clinics are usually held in June.

State Medical Election—Dr Cleveland Thompson, Millen, was chosen president-elect of the Medical Association of Georgia at its annual meeting, May 14, and Dr William A. Schman, Atlanta, was installed as president. Dr Edgar D. Shanks, Atlanta, is the secretary-treasurer. The next annual session will be held in Savannah, May 9-12, 1944.

ILLINOIS

Personal—Dr George W. Nesbitt, Syracuse, received a fifty year certificate and gold emblem on March 25 at a dinner of the De Kalb County Medical Society. Dr Clifford E. Smith is secretary of the society.—Dr Philip D. McGinnis has been appointed health officer of Joliet.

Chicago

Personal—Mr J. Dewey Lutes, formerly superintendent of the Presbyterian Hospital, has been named administrator of a new general hospital to be erected in Bethesda, Md., with funds provided by the Lanham act.—Dr Oswald H. Robertson, professor of medicine at the University of Chicago School of Medicine, has been elected to membership in the National Academy of Sciences.—John M. Storm, associate editor and chief editorial writer of the *Cleveland News*, has been named managing editor of *Hospitals*, effective May 1. *Hospitals* is the official publication of the American Hospital Association.

Cancer Prevention Clinic—A cancer prevention clinic for women has been opened at the Women and Children's Hospital, 1600 West Maypole Avenue. The clinic, which is staffed entirely by women physicians, will operate under an advisory committee comprising Drs James P. Simonds, chairman, Bowman C. Ciowell, Frederick H. Falls, Augusta Webster and John A. Wolfer. Dr Webster is also chairman of the clinic staff. The hospital supplies the space and equipment, and the Women's Field Army of the American Society for the Control of Cancer furnishes a volunteer graduate nurse, a nurse's

aide, medical social workers and clerical assistance, pays the hospital for certain services and makes the appointments for the examinations. Patients who are able to pay are charged a \$5 fee that covers laboratory and fluoroscopic charges only. Free examinations are given to those who cannot afford to pay. Reports of diagnoses are sent to the patients' physicians. The Illinois Federation of Women's Clubs has given \$1,000 to the Women's Field Army as a contribution toward the clinic. Inquiries and applications for appointments at the clinic should be directed to the Women's Field Army, 48 West Division Street.

INDIANA

Tropical Medicine Program Initiated at Indiana University—The appointment of William H. Headlee, Ph.D., as assistant professor of parasitology in the Indiana University School of Medicine, Indianapolis, marks the introduction of a new program for the study of tropical medicine at the school. The launching of the program follows a recommendation of the Association of American Medical Colleges. In making the announcement Dr Willis D. Gatch, dean of the medical school, explained that the step had been taken, first, to prepare the future army and navy physicians now being trained in the Army Medical School for service in the tropical regions and, second, is a precaution against the introduction of rare tropical diseases in the United States. Dr Headlee graduated at Earlham College, Richmond, in 1929. At one time he taught at Purdue University, Lafayette, and served as a Rockefeller Foundation fellow at the Institute of Tropical Medicine, Tulane University of Louisiana, New Orleans, from 1932 to 1934, where he received his Ph.D. in 1935. He also spent a year as biologist and parasitologist in Venezuela, where he drew up the plans for the laboratories of the new Institute of Tropical Medicine at Caracas.

KANSAS

Zoologist to Study Vitamin E—Earl H. Herrick, Ph.D., professor of zoology and mammalogist of the Agricultural Experiment Station at Kansas State College of Agriculture and Applied Science, Manhattan, has been awarded the Elizabeth Clay Howard Scholarship of the Ohio State University, Columbus. Under the scholarship, which carries a stipend of \$1,000 for the year, Dr Herrick will devote his time to the study of vitamin E in relation to function of the anterior pituitary.

Annual Registration Due Between July 1 and October 1—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually between July 1 and October 1 and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

MAINE

Annual Gerrish Library Lecture—Dr Charles Sidney Burwell, dean of the Harvard Medical School, Boston, delivered the sixth annual Gerrish Library Lecture at the Central Maine General Hospital, Lewiston, May 14. His subject was 'Changing Viewpoints as to Disorders of Circulation'.

Medicolegal Meeting—"How Far Should the State Go in Taking Over from the Counties in Homicide Cases?" was the theme of the annual meeting of the Maine Medico Legal Society at the Augusta House, June 20. Franz U. Burkett, Portland, former attorney general, opened the discussion.

MICHIGAN

Student Scholarship Established—The Theodore A. McGraw Memorial Scholarship, to be awarded to the outstanding junior student in the Wayne University College of Medicine, Detroit, has been established as a memorial to the late Dr McGraw, at one time president of the college when it was known as Detroit College of Medicine and Surgery. The award is the gift of Dr James D. Bruce, Ann Arbor, and will amount to \$100 annually. Dr McGraw died in 1921.

Health Director Goes to Alaska in Charge of Maternal and Child Health—Dr N. Berneta Block, director of the Alger-Schoolcraft health department, has accepted a position as director of the maternal and child health service of the territory of Alaska, newspapers reported, June 3. Prior to her appointment in February as acting director of the health unit, Dr Block had been regional consultant in maternal and child health in Lansing. In her new position she will direct maternal and child health services throughout Alaskan territory. Her headquarters will be in Juneau.

Upper Peninsula Medical Meeting—The forty-sixth annual meeting of the Upper Peninsula Medical Society will be held at the Pine Grove Country Club Iron Mountain July 14 with the Dickinson-Iron County Medical Society acting as host. Among the speakers will be:

Dr. Alexander M. Campbell, Grand Rapids, The Abortion Problem
Dr. Lidden J. Teeter, Indianapolis, Anemias
Dr. Harry R. Foerster, Milwaukee, Occupational Dermatoses
Dr. Howard H. Cummings, Ann Arbor, Endometriosis
Dr. John M. Waugh, Rochester, Minn., Vaginal Hysterectomy
Dr. Herman C. Schumm, Milwaukee, Methods of External Fixation
Dr. Reed M. Nesbit, Ann Arbor, Diseases of the Prostate Gland

MONTANA

Personal—Dr. Walter V. McPhail, Missoula, has been appointed director of the health service at Montana State University for the winter quarter.—Dr. Curtis W. Wilder, Lewistown, has been named health officer of Fergus County to succeed the late Dr. Charles C. Wallin. Lewistown. Dr. Wallin held simultaneously the position of county health officer and Lewistown city health officer and full time school physician. The two latter posts had not been filled at the time of this report.

NEW YORK

Tuberculosis and Diseases of the Chest—A teaching day on tuberculosis and diseases of the chest will be held at Onondaga Sanatorium, Syracuse, July 9 under the auspices of various county medical societies and other local health groups including the Syracuse University College of Medicine and the department of health state medical society and state department of health. Speakers will include:

Dr. Reuben J. Erickson, Albany, Pulmonary Tuberculosis: Early Diagnosis and Differential Diagnosis
Dr. Irl H. Blassdell, Syracuse, Bronchoscopy as a Diagnostic Aid in Diseases of the Chest
Dr. Ethan Flagg Butler, Ithaca, Common Thoracic Emergencies
Drs. J. Maxwell Chamberlain, Oneonta, and Edward Sawtelle, Welles, Saranac Lake, Surgical Treatment of Pulmonary Tuberculosis
Drs. Butler and Albert G. Swift, Syracuse, Surgical Treatment of Non-tuberculous Lung Conditions

New York City

Dr. Sebrell Gives Rothschild Lecture—William H. Sebrell Jr., surgeon, U. S. P. H. S., Bethesda, Md., delivered the Marcus A. Rothschild Lecture at Beth Israel Hospital, June 15, on 'Trend of Recent Research in Vitamins and Clinical Symptoms of Vitamin Deficiency.'

Course in Ophthalmology Discontinued—The New York University College of Medicine, department of ophthalmology, announces that because of the educational program associated with the war effort the nine months graduate course in ophthalmology will be discontinued for the duration of the war.

Health Department Secretary Appointed—Matthew A. Byrne has been appointed secretary of the city department of health to succeed Dr. Frank A. Calderone, who recently was appointed deputy health commissioner in the department. The appointment was made on the fortieth anniversary of Mr. Byrne's service in the department. In his new position he will supervise the administrative activities of the department and will continue as a member of the personnel board.

OHIO

State Welfare Director Resigns—Charles L. Sherwood, Fremont, has resigned as state welfare director to become a member of the Ohio Pardon and Parole Division effective June 15. Assistant director of the department of welfare in 1929 and 1930, Mr. Sherwood formerly was secretary of the Ohio Council of Public Welfare, associate director of the Ohio Institute for Governmental Research and executive secretary of the Ohio Mental Hygiene Association. He has been state welfare director since 1939.

New Method of Handling Sale of Medical Liquor—On June 1 when the state liquor stores were reopened under the rationing of sales to the public, a new method of handling the sale of liquor for medicinal purposes became effective in Ohio. According to the state medical journal it is anticipated that the amount which may be purchased by any holder of a liquor ration book will be sufficient to meet the medicinal needs of many persons for whom liquor will be prescribed by the attending physician. However, in the event that an additional amount is needed for bona fide cases in which the uniform allowance under the rationing program is insufficient a specified additional amount may be purchased on the presentation of a lawfully issued prescription by a duly licensed Ohio physi-

cian and bearing the stamp of approval of the state liquor director. The prescription should be mailed by the physician or patient to the state liquor director. It approved it will be so mailed and returned to the patient. In urging the cooperation of physicians in the new plan, the state medical journal suggests that physicians not only minimize the prescribing of medicinal liquor but likewise minimize the amounts when prescribing is necessary. The regulation states that the amounts prescribed shall be for a period not to exceed one month.

PENNSYLVANIA

Society News—Dr. Oscar V. Batson, Philadelphia, discussed 'Maxillofacial Emergencies' before the Reading Eye, Ear, Nose and Throat Society in Reading recently.—Dr. Thomas A. Lambie, Harrisburg, formerly personal physician to Haile Selassie, emperor of Ethiopia, discussed 'Medical Practice in Ethiopia' before the Northampton County Medical Society, June 18.

Philadelphia

Indictments Charge Theft of Army Medicine—On May 28 indictments charging participation in private sales of 53,000 sulfadiazine tablets intended for army use in combating tropical fevers and pneumonia were returned by a federal grand jury against a physician, seven druggists and six other persons. According to the New York *World Telegram*, the thefts were said to be discovered by an employee of the manufacturing firm of Sharp & Dohme, Inc., who recognized army markings on a bottle or tablets he saw on a drug store shelf. According to the *World Telegram*, those indicted were Dr. John Leonard Brill, 37, charged with conspiracy and receiving stolen tablets; three Sharp & Dohme employees, Alton C. Master, James Jones and James A. Garry, charged with conspiracy and theft of the tablets; Sidney J. Mervise, Joseph Sotter, David R. Vasper, David Masters, Irving Kramer, Meyer Joseph Rosenfeld and Jacob M. Berenbaum, druggists, all charged with conspiracy and receiving stolen tablets; and William Evans, charged with selling; James E. Williams, charged with delivering; and Anthony Frankina, charged with assisting in the deliveries.

WEST VIRGINIA

New Director of Industrial Hygiene—Dr. Charles S. McKinley, Scotch Plains, N. J., has been appointed director of the bureau of industrial hygiene in the state department of health. His appointment was made on the recommendation of the U. S. Public Health Service. He succeeds Dr. John W. Crosson, who recently resigned to become industrial consultant for Sharp & Dohme, Philadelphia (THE JOURNAL, March 6, p. 776).

Regulations for Control of Cancer and Tuberculosis—Regulations governing the operation of the new division of cancer control in the state department of health were approved by the Public Health Council at a meeting in Charleston, June 16-17. Standards for the qualifications of the director, assistant director and educational consultant of the new cancer division were set up by the council in consultation with the Merit System Council as required under the provisions of the cancer control bill passed at the 1943 session of the legislature. The director and assistant director must be qualified to practice medicine in West Virginia. In addition, the director must have had at least two years postgraduate training, one devoted to the treatment and cure of cancer and the other to pathology, or two years work in the field of cancer. It was also specified that the director must acquire a degree in public health within the period of three years after his appointment. The new division will be tied in with the West Virginia chapter of the Women's Field Army of the American Society for the Control of Cancer. A survey will be started at once to determine what clinics in the state can carry on the work incident to the diagnosis and treatment of cancer. Approval of the clinics will be given on the advice and counsel of the cancer control committee of the West Virginia State Medical Association. Standards now used by the department of public assistance will be used to determine the eligibility of a patient for treatment or care.

An investigation will be made within the next sixty days by the department of public assistance of all persons now in state tuberculosis sanatoriums to ascertain whether they are really needy and entitled to payment for treatment. The population of state tuberculosis institutions is now 901. After July 1 the state will be required to expend \$1 a day for each person for the continued treatment of the needy at these institutions. Under

the regulations adopted, the physician who believes that a needy tuberculous patient requires hospitalization should report to the local health officer. The patient will then be investigated by a field visitor of the department of public assistance, a representative of the West Virginia Tuberculosis and Health Association and three citizens of recognized standing in the community. Final approval will be given by an advisory committee consisting of three tuberculosis specialists who are members of the state medical association, together with a lay representative of the West Virginia Tuberculosis and Health Association. Unless it is an emergency case, the hospitalization request will be referred to the department of health for review.

WISCONSIN

Rocky Mountain Spotted Fever—What appears to be the first proved case of Rocky Mountain spotted fever in Wisconsin is reported in an original article in the state medical journal for June. The patient was being treated in May 1942, but public reporting was purposely delayed until the spring months so that the picture and methods of diagnosis would be vivid at a time when the disease becomes most prevalent, according to the state journal. The article points out that in June 1942 Wisconsin was reported as one of the few states remaining free from spotted fever.

GENERAL

Program on Industrial Eye Hygiene—Joseph LoPresti, Brooklyn, assistant surgeon, U. S. Public Health Service Reserve, has been assigned to the National Society for the Prevention of Blindness to carry on a program in the field of industrial eye hygiene. A release from the National Society stated that the addition of Dr. LoPresti to the staff will enable the society to develop more thoroughly its activities in the field of industrial eye hygiene. The appointment of Dr. LoPresti will also assist the society in cooperating more extensively with the medical profession and particularly with industrial physicians and industrial hygiene directors. Dr. LoPresti graduated at New York University College of Medicine in 1940.

New Grants in Tropical Medicine—The American Foundation for Tropical Medicine recently authorized grants to six North American medical schools totaling \$26,100. The grants, made possible by contributions and pledges during the current year of \$60,100 by nineteen American corporations, are being used to strengthen teaching or research programs in tropical medicine and parasitology at the various schools. The approved projects were selected by the medical committee of the foundation among a number of applications. The medical schools to receive aid were:

New York University College of Medicine, salary aid for full time instructor in tropical medicine and parasitology.

Tufts College Medical School, Boston, to employ clinical teaching fellow in tropical medicine.

Tulane University of Louisiana School of Medicine, New Orleans, budgetary needs of department of tropical medicine, which has trained forty-one physicians from Central and South American countries, from Africa and from Asia since 1940.

University of Manitoba Faculty of Medicine, Winnipeg, traveling fellowship for professor of parasitology and tropical diseases.

University of Nebraska College of Medicine, Omaha, for full time technical assistant to assist teaching in student laboratories and staff research.

Yale University School of Medicine, New Haven, Conn., to supplement salaries of teachers and laboratory assistants in order to expand tropical medicine teaching.

Other applications are pending, it was stated, and those which are approved will be financed out of the contributions. The foundation's program, adopted at the annual meeting of members in January, calls for the collection and disbursement of \$100,000 among medical schools and scientific journals and for special projects which fall within the scope of the foundation's activities.

Special Society Elections—Dr. Frederick A. Collier, Ann Arbor, Mich., was chosen president of the American Surgical Association at a special executive session on May 14. Other officers include Drs. Urban Maes, New Orleans, and Arthur M. Shipley, Baltimore, vice presidents, Warfield M. Firor, Baltimore, secretary, and Leland S. McKittrick, Boston, treasurer.—Dr. Ross Golden, New York, was elected president of the American College of Radiology at its meeting in Chicago on June 6 and Dr. Lyell C. Kinney, San Diego, Calif., vice president. Dr. Hollis E. Potter, Chicago, was reelected treasurer and Mac F. Cahal, Chicago, executive secretary. Dr. Lowell S. Goin, Los Angeles, is chairman of the board of chancellors of the college.—Dr. Calvin A. Walker, San Francisco, was chosen president of the Western Association of Industrial Physicians and Surgeons at its recent annual meet-

ing. Other officers are Dr. Rutherford T. Johnstone, Los Angeles, who was reelected secretary, Dr. James M. McCullough, Crockett, Calif., treasurer, and Elizabeth M. Caffrey, P. H. N., Crockett, who was reelected executive secretary.—Robert D. Potter, New York, science editor of the *American Weekly*, was elected president of the National Association of Science Writers at the annual meeting held in Chicago at the time of the annual session of the House of Delegates of the American Medical Association. He succeeds Watson Davis, Washington, D. C., director of Science Service. Capt. Stephen J. McDonough, M. A. C., of the Office of the Surgeon General of the Army, was reelected secretary-treasurer.

CANADA

Summer School—The Vancouver Medical Association conducted its summer school in the Vancouver Hotel, Vancouver, B. C., June 22-25. Among the speakers were:

Brig. Jonathan C. Meakins, R. C. A. M. C., Effort Syndrome and Allied Conditions in Civil and Military Practice.

Dr. Edwin M. Robertson, Kingston, Ont., Prolapse of the Pelvic Organs.

Dr. Maxwell M. Canton, Edmonton, Alta., The Clinical Application of Research in Nutrition.

Dr. Foster Kennedy, New York, Allergic Manifestations in the Nervous System.

Lieut. Col. Gordon S. Fahrm, R. C. A. M. C., The Newer Concepts in the Treatment of Wounds.

Lieut. Col. James D. Adamson, R. C. A. M. C., Chronic Nontuberculous Pulmonary Disease in the Army.

Dr. Brien T. King, Seattle, with others, participated in a round table discussion on "Thyroid Disease." Dr. Kennedy also addressed a luncheon on "De Propaganda Fide."

LATIN AMERICA

Costa Rica Venereal Program—Dr. Jose Amador Gutierrez has been appointed to head a reorganization program of venereal disease control in Costa Rica, according to the War Letter. Dr. Amador's title is chief general of the antivenereal disease campaign. He received his training under the Rockefeller Foundation.

Otorhinolaryngologic Congress—The second Latin American Congress of Otorhinolaryngology will meet at Montevideo in 1944 under the presidency of Dr. Justo M. Alonzo, the exact date to be announced later. Dr. Juan Carlos Oreggia, Calle Y 1491, Montevideo, Uruguay, is the general secretary of the executive committee.

Deaths in Other Countries

Sir Arthur Newsholme, London, public health authority and author of numerous medical works, died on May 17 at his home in Worthing, Sussex, aged 86. He graduated at London University in 1881. Sir Arthur was a lecturer at Johns Hopkins University, Baltimore, in 1919. In 1928 he was in New York to act in a consulting capacity with the department of health. During his career he served as medical officer of health of Brighton, examiner in public health at Cambridge University, examiner in preventive medicine at Oxford University and examiner in state medicine, University of London. In 1901 he was president of the Society of Medical Officers of Health and was a former principal medical officer of the British Local Government Board.—**Alfred Erich Hoche**, director of the psychoanalytic clinic of the University of Freiburg, died May 17, aged 77. Dr. Hoche was at one time professor of psychiatry at Freiburg.—**Peter Muehlens**, professor and director of the Hamburg Institute for Tropical Diseases, died in Hamburg recently, aged 69.

Government Services

Food Rationing Problems of Hospitals

Leighton M. Arrowsmith, administrator of the St. John's Hospital in Brooklyn, has been appointed head of the hospital unit in the institutional user branch of the food rationing division, Office of Price Administration. Mr. Arrowsmith will be concerned principally with the food rationing problems of hospitals and similar institutions. He has been administrator of St. John's Hospital for fourteen years and during that time has been president of the Hospital Council of Brooklyn, president of the Greater New York Hospital Association and for the past three years president of the Hospital Bureau of Standards and Supplies. He is also active on the simplification and standardization committee of the American Hospital Association.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 22 1943

Lord Dawson on the Proposed State Medical Service

Lord Dawson formerly physician to the London Hospital, outlines in the *Times* a plan for the future health service. There is general agreement he says, that all methods of treatment should be available to every citizen but the future service should be built on and not destroy existing foundations. Its evolution should be gradual in the light of accrued experience. A prime desideratum is that preventive and curative medicine be brought together and be included in the education and practice of every teaching hospital. To secure areas of sufficient size for hospital services it will usually be necessary to combine several existing major local authorities into a new health authority under which the hospitals would work. There would be a key hospital or the area toward which the services would look for leadership and advice. If available a teaching hospital would fulfil this purpose.

These services will involve considerable changes in the duties both of the local authority and of the medical profession. For local government to be the ultimate administrative authority would conform not only with our constitutional usage but also with the fact that it is already responsible for the health services and its own hospitals. But the medical profession and the voluntary hospitals should not be expected to accept this unless such an administration for complex health and hospital service is guided by representative expert advice. This difficulty could be resolved as follows: 1 The larger outlines of policy should be laid down at the center with the aid of an advisory board representing the parties and including a large proportion of physicians. 2 Following the precedent of education the health authority should contain a minority of members chosen or nominated. 3 Corresponding to each health authority should exist an advisory body to give skilled guidance on medical and hospital policy. Like the central body it would consist of representatives of local authorities, voluntary hospitals and physicians.

Hospital and consultant services should be remunerated by appropriate salaries. Private practice though independent should be coordinated with the fabric of the service. Otherwise there would develop two sets of doctors and a divided profession. Pay beds—with the same treatment as other beds but with added amenities—are consistent with equality of opportunity. Of the whole time state salaried service for all doctors which is strongly favored by the labor party Lord Dawson says that it would make a tidy though rigid administrative machine, but man is not a machine, least of all the sick man. It would give doctors fixed hours but illness has no fixed hours. In this letter to the *Times* Lord Dawson has dealt with what are likely to be the most contentious points between the medical profession and the government.

Transfusion Accidents to Be Investigated

The Blood Transfusion Research Committee of the Medical Research Council has drawn up a memorandum for circulation by the Ministry of Health to hospitals and maternity services. If following transfusion the state of any patient gives rise to anxiety which can reasonably be ascribed to the transfusion, it is requested that the incident be immediately reported by telephone to the nearest blood supply depot in the London area or regional transfusion laboratory in the provinces, so that the necessary investigations may be initiated at the earliest possible moment. At the same time the hospital pathologist should be informed. The conditions which it is particularly desired to

investigate are hemolytic reactions due to deterioration or contamination of the blood or blood derivatives used for transfusion. Although the clinical picture is variable, it is suggested that sudden grave collapse, acute severe backache, hemoglobinuria or jaundice should be notified. Investigations would be made much easier if a sample of the blood or blood derivative from the bottle was available. It is therefore requested that a few cubic centimeters should be left in every bottle of transfusion fluid and kept for at least twenty-four hours and not thrown away until the patient has been revisited and it has become clear that he has not reacted unfavorably to the transfusion. As a routine, therefore, every bottle should be recapped and put in a refrigerator. If for any reason immediate contact with transfusion headquarters is impossible, a sample of the blood should be withdrawn from the patient under sterile conditions, with a dry syringe if possible, and divided between two dry sterile tubes and one dry oxalate tube for blood culture and other examinations. At the same time a clean specimen of the urine should be obtained from the patient and kept. In the ordinary course these specimens will be collected by the transfusion officer when he arrives to see the patient.

The Employment of Native Physicians in the West African Medical Service

The British government's plans for the reorganization of the colonial services include the employment of an increasing number of native officers in the West African medical service. At the annual meeting of the League of Colored Peoples, held in Liverpool, a letter from Mr. Oliver Stanley, secretary of state for the colonies was read in which he asked the league to believe that the Colonial Office had been actuated by a genuine design to abolish racial discrimination in the public service. Looking to the future we now could and should envisage a situation in which medical services would be mainly staffed by officers of local origin who had obtained their qualifications in West Africa. The present stage was one of transition, and no doubt for some time to come the medical services would include a strong element of European officers. But there was an increasing element of West African officers and he had every intention that this should expand as rapidly as possible. The Colonial Office was making plans for the reorganization of the colonial services, which it would be premature to disclose but which were designed to eliminate the difficulties to which the league had drawn attention. Thus the British have established in West Africa a medical school for the education of the natives who are now in increasing numbers taking the place of Europeans in the local medical service. That such a development is taking place in one of the most primitive peoples who have come under British rule is a striking testimony to the nature of this rule.

New Research Chair in Ophthalmology

The Royal College of Surgeons has founded a research chair in ophthalmology tenable at the Royal Eye Hospital Southwork (in London). It is the first chair of the kind in this country and the hospital has undertaken to raise \$200,000 for its permanent endowment. The holder of the chair will devote the whole of his time to clinical research at the hospital and to laboratory work at the Royal College of Surgeons.

The Lowest Maternal Mortality on Record

Though we have the usual wartime increase in venereal diseases and tuberculosis, we have also been able to record some actual improvements in the public health during the war. The latest is that the maternal mortality rate for 1942 is the lowest on record. It was 2.47 per thousand births. This compares with 2.77 for 1941 and is little more than half the rate of 4.41 for 1934. That is a fine tribute to the work of midwives, says

the minister of health. The number of maternity beds available has increased by more than 3,000, but the number does not keep pace with the growing demand under wartime conditions. There is shortage of midwives, which prevents more maternity beds from being opened.

BRAZIL

(From Our Regular Correspondent)

June 1, 1943

Hepatic Lesions in Infections by *Schistosoma mansoni*

Dr Eudoro Villela of Laboratory of the Brazilian Yellow Fever Service made a comparative study of *Schistosoma mansoni* microscopic lesions observed in 6,000 cases out of 150,000 liver specimens which were collected through the work of viscerotomy between 1930 and 1938. As reported in a previous letter, a medical representative of the Yellow Fever Service takes a small specimen of the liver, with the aid of the viscerotome whenever a case of death occurs after an illness of the maximum duration of ten days, in the little towns of the hinterland of Brazil. All the liver fragments, measuring an average of 2 by 1 by 1 cm. are immediately fixed in 10 per cent solution of formaldehyde. In the laboratory they are embedded in paraffin, cut to be 4 to 6 microns thick and generally stained by hematoxylin-eosin. For the study of the reticulum and collagen network the silver double impregnation method after Del Rio Ortega has been used in frozen specimens. The author himself recognizes the disadvantages inherent in the microscopic study of small fragments of the liver, but he believes that in spite of this the high number of specimens examined may enable him to draw from such a study valuable information regarding the hepatic pathology of visceral schistosomiasis. So constantly does the liver present lesions in the case of infection by *Schistosoma mansoni* that Lambert considers the routine microscopic examination of the organ the best way to express the schistosoma infection index of a given locality. Since the early phases of the infection small forms of *Schistosoma* are found in the lumen of the intrahepatic portal vein ramifications, and later eggs, toxins and pigments are discharged by the helminths in the blood stream. All these elements can harm the hepatic tissue, causing lesions the nature and intensity of which may vary according to the degree of infection and the time elapsed since its beginning. One of the most important contributions on this subject is that of Koppisch (Puerto Rico, 1937), who described the pathologic changes caused by experimental infection of the rabbit and the albino rat by *Schistosoma mansoni*. Koppisch ascertained that in the experimental infection the most frequent changes result particularly from the presence in the liver of the helminths, and their toxins and pigments, the eggs taking a minor part in the causation of the lesions. He found out that the embryos die immediately after the laying of the eggs, as the shells found in the liver are almost always empty. According to him this fact explains the rarity of the presence of pseudotubercles in the rabbit and in the albino rat, in contradistinction to what occurs in man, in whose infection the pseudotubercle is the fundamental lesion of visceral schistosomiasis. This is the consequence of the great resistance of the embryos in the interior of the egg, which is attested by the perfect chromophily of its internal structure. It seems therefore that the pathogeny of the liver lesions in the human infection is different, as the schistosomes are seldom found in the intrahepatic ramifications of the portal vein, and in this manner the products probably discharged by the helminths might not have any important role in the causation of the changes.

The lesions found in Dr Villela's investigation may be separated into three great classes. The first class includes the lesions that may be attributed to the probable toxins secreted

by the schistosomes, the most frequent being hyperemia of the hepatic venous sinuses, cloudy swelling, fatty infiltration and necrosis of the centrilobular zone. Acute or subacute liver atrophy has been found in but few cases, and the author is inclined to believe that the lesion was caused by the schistosome infection. Only once did he find, in the liver of a child, lesions appearing to be produced by yellow fever, but the clinical history of the cases revealed that the changes were caused by subacute antimony poisoning (fuadin). The second class of lesions includes the changes produced by the eggs of the helminth. In the human infection the eggs enter the liver through the portal vein, and in the initial phase of the disease they are generally found in the little veins of the portal spaces and in the venous sinuses, but rarely in the centrilobular veins. The most frequent lesions caused by the presence of the egg are the reactions of foreign body around the empty egg (gigantic cell and monocytic infiltration) and around the egg with living embryo (pseudotubercle) as described since 1931 by Brumpt and Chevalier. Several cases have been found by Dr Villela presenting a proliferative reaction with the structure of a pseudoabscess round the egg with living embryo. The egg is encircled by a layer of eosinophil and mononuclear cells with epithelioid cells in the periphery, but there is no zone of cellular rarefaction immediately round the egg. The area occupied by the pseudoabscess is larger than the corresponding one in the ordinary reactional process. This type of lesion has been identified by the author as an allergic reaction of the human organism to the material discharged by the embryo. Dr Villela's interpretation of this type of lesion is based on the findings of K. B. Kerr, who described abnormally intense reactions in the liver and in the lungs of guinea pigs, the nature of which to the experimental porcine ascariasis had been incited by a previous infection by *Ascaris suum*. Kerr, Coventry and others attribute this cellular reaction to an allergic manifestation, as Mainz and Pons had already described some human cases of urticaria and bronchial asthma associated with the infection by schistosoma. Dr Villela found also a few cases of a type of lesion never before described in the human infection by *Schistosoma mansoni* but previously reported by R. Hoeppli in the infection by *Schistosoma japonicum*. It is a pseudotubercle with stripes, intensely stained by eosin, irradiating from the egg shell. This oxyphilic substance has a strong necrosing power and, according to Hoeppli, is secreted by the lateral glands of the embryo. In some cases pseudotubercles of this type occurred side by side with reaction of the allergic type round eggs with living embryos. Dr Villela believes that despite the impossibility to affirm that this state of hypersensitivity of the liver tissue may be caused by the oxyphilic matter, the coincidence of the two conditions in the same individuals is worth mentioning. The third class of liver lesions caused by the schistosoma infection includes the fibrous type of reaction of which there are two kinds. The first kind of schistosomal liver fibrosis consists in the simple formation of fibrous tissue round the pseudotubercles located in the portal spaces. The second kind is represented in the early stage by the thickening of the reticulum fibers between two or more pseudotubercles. This process, called by Villela "reticulum sclerosis," immediately precedes the real fibrotic degeneration. When the process of fibrosis reaches the stage in which two or more portal spaces invaded by the eggs are united, an irregular network of trabeculae is formed, sometimes seen macroscopically under the aspect of the so-called claypipe stem cirrhosis or even portal cirrhosis, as has been described by W. S. C. Symmer. Dr Villela describes for the first time a type of lesion that he calls "circumscribed cirrhosis," represented by a fibrotic process that irregularly outlines a few lobules or pseudolobules in a determined zone of the liver, but he believes it is not easy to explain why the process of cirrhosis remains circumscribed.

The Scheme for a Salaried Medical Practitioner Service

The National Health and Medical Research Council was established in 1957 by the federal government, its function being to promote the health of the people of Australia and to advise, coordinate and direct research into the cause and cure of disease. The council consists of representatives of the commonwealth and state departments of health, Australian universities having medical schools, the Royal Australian College of Surgeons, the Royal Australian College of Physicians, the Federal Council of the British Medical Association in Australia and one layman and one laywoman appointed by the federal government.

In May 1941 the council appointed a subcommittee to prepare a report on the most effective organization for the preservation of the health of the people of Australia. The preliminary report drawn up by this committee presented an admirably broad and lucid exposition of the question and is well worthy of study in other countries where projects for the reconstruction of medical practice are being considered. In this report it was claimed that a complete and efficiently organized system of hospital and medical health services could be provided at a cost easily within the capacity of the community and that the council was prepared to furnish practical details and to support these with evidence as to revenue and expenditure.

The federal government asked the council to give some indication of the general lines along which such a change could proceed and accordingly the council presented a report drawn up by its subcommittee giving an Outline for a Possible Scheme for a Salaried Medical Service. This has been described as the most important document ever received in dumb silence by the medical profession in Australia. The scheme provides for a complete salaried medical and hospital service for the commonwealth which would be under the control of the federal government and includes all aspects of preventive and curative medicine. The whole of the populated areas of Australia are divided into health districts each of which would be controlled by a district health officer appointed by the federal government. The scheme is based on (a) the district hospital system (each hospital district coinciding as far as possible with a health center) and (b) the group system of medical practice with special provision of specialist services. There is a complete gradation and coordination of medical and hospital services from those suitable for small country areas to the organization required in large cities. The unit of medical practice is the consultation center, which is also the center for preventive and protective medical services. Consultation centers are graded according to population and medical requirements and range from one man medical practitioner centers in small country districts to larger centers in towns provided with hospital facilities. These in turn link up with district divisional centers which would be the bases for health and administrative as well as for the clinical and specialist services for the district. Maternal and child welfare centers, school medical services and other similar health agencies will have their headquarters at the district centers. Medical specialists are organized into district consultant specialist services each group of specialists being available to one or more of the divisional centers. In metropolitan areas there will be a base hospital to be kept for serious and specialist cases and a ring of subsidiary hospitals reinforced by consultation centers staffed by groups of general medical practitioners. These centers will deal with the large mass of general practice now constituting 'outpatient' practice at general hospitals. Domiciliary visiting will not be encouraged but a certain amount will be necessary. The council

considers that the whole scheme is not inconsistent with the retention of private practice.

The scheme has been severely criticized by members of the medical profession in that among other things, it was not drawn up by a body familiar with the actual needs and problems of medical practice. On the other hand in its report the council has stated that the medical profession should be fully consulted on all points raised in the outline and that this was not intended as a final and complete scheme but as 'a basis for discussion of a reconstructed relationship between the government, the people and the medical profession'. As such it is being used by the Joint Parliamentary Committee on Social Security which is at present taking evidence from medical men in the different states on the question of medical and associated practices.

Control of Proprietary Medicines

After having been in operation for several months, the National Security (Proprietary Medicines) Regulations have been disallowed by the federal parliament. Since the introduction of the regulations in October 1942 a great deal of controversy has ensued and the validity of the order has been questioned. Certain amendments were brought into force in January 1943 but the opposition to the regulations still continued and on February 16 it was moved in the House of Representatives that the National Security (Proprietary Medicines) Regulations made under the National Security Act 1939-1940 be disallowed. There followed a lengthy debate which was adjourned before completion and resumed on March 5 when the issue was put to the vote. Mr Spender who moved the motion said that there were only two grounds on which the regulations could be justified (1) conservation of drugs in short supply and (2) conservation of manpower. The regulations could not be justified from either point of view because the government had already provided itself with adequate powers by other regulations under the National Security Act to cope with both these problems. When the regulations were examined he said it was clear that they were not designed primarily as a wartime measure to conserve materials and economize the use of manpower but that the real reason for their introduction was related to the matter of public health.

The principal clause in the regulations empowered the minister for health to ban the manufacture and sale of any proprietary medicine which in his opinion did not possess the qualities claimed for it. The supporters of the motion for disallowance of the regulations objected to judicial power being vested in executive officers or their nominees and claimed that such a prohibition desirable though it might be in the interests of public health could scarcely be justified on the grounds of wartime necessity or the conservation of manpower and materials. The validity of the regulations depended on whether it could be shown that they had some connection with the war effort. On the question being put the motion for the disallowance of the regulations was carried by a majority of one.

Marriages

ROBERT CLARK DAY New Orleans to DR. IAN MAYHEW MATTHEWS of Montgomery Ala. at Camp Cooke Calif. June 8

CLOYCE FLOWERS BRADLEY Powell Tenn. to Miss Mary McPheeters Jarnagin of Jefferson City in May

ERNEST HAROLD KING to Miss Marge Goodwin both of Los Angeles at Santa Monica Calif. June 12

SPENCER ALLEN TRUEX JR. Jackson, Tenn. to DR. BARBARA MAE BINKLEY of Nashville recently

SAMUEL S. ALLEN Robinson Ill. to Miss Bernice Quick of Oblong June 3

NIELS L. LOW to Miss Mary Margaret Cook both of Milwaukee May 29

Deaths

Arthur Trautwein Henrici, Minneapolis, University of Pittsburgh School of Medicine, 1911, instructor in pathology and bacteriology at the University of Minnesota Medical School from 1913 to 1916, assistant professor of bacteriology from 1916 to 1920, associate professor from 1920 to 1925 and since 1925 professor of bacteriology and immunology, professor of bacteriology and immunology at the University of Minnesota Graduate School, in 1941 Wilker-Ames professor of bacteriology at the University of Washington, Seattle, member, past president and vice president of the Society of American Bacteriologists, member of the Society of Experimental Biology and Medicine, Linnological Society of America and the Mycological Society of America, served as a captain in the medical corps of the U. S. Army from 1917 to 1919, author of "Morphologic Variation and the Rate of Growth of Bacteria," 1928, "Molds, Yeasts and Actinomycetes," 1930, and the "Biology of Bacteria," 1934, second edition published in 1939, aged 54, died, April 23, in the University Hospital of coronary thrombosis.

Carl Wesley Apfelbach ♂ Chicago, Rush Medical College, Chicago, 1922, professor of pathology at the University of Illinois College of Medicine, formerly associate and assistant professor of pathology at his alma mater, specialist certified by the American Board of Pathology, Inc., member of the Central Society for Clinical Research, American Association of Pathologists and Bacteriologists, American Society for Experimental Pathology, American Society of Clinical Pathologists, American Association of Cancer Research and the International Society of Medical Museums, in 1942 appointed medical director of the Presbyterian Hospital, where he had been a member of the staff since 1924, for many years attending pathologist at the Cook County Hospital, aged 49, died, June 25.

John Barnwell Elliott, Birmingham, Ala., Medical Department of Tulane University of Louisiana, New Orleans, 1894, member of the Louisiana State Medical Society, specialist certified by the American Board of Internal Medicine, an emeritus professor of the theory and practice of medicine and for many years a member of the board of administrators at his alma mater, served as a lieutenant colonel in the medical corps of the U. S. Army in France during World War I, received the honorary degree of doctor of laws from Tulane University in 1937, aged 72, died, April 14, of myocarditis, hypertension, arteriosclerosis and cerebral hemorrhage.

Albert Frederick Spurney ♂ Cleveland, Western Reserve University Medical Department, Cleveland, 1887, formerly associate professor of gynecology and obstetrics at the Cleveland College of Physicians and Surgeons, fellow of the American College of Surgeons, one of the founders of the Cleveland Medical Library, served on the staff of the Cleveland City Hospital, a member of the building committee, active on the surgical staff, and chief of staff of St. Luke's Hospital, superintendent and president of the board of trustees of the Polyclinic Hospital, where he died, April 15, of hypertrophy of the prostate, aged 77.

Jules Victor Haberman, New York, Columbia University College of Physicians and Surgeons, New York, 1905, Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1908, instructor in neurology at Columbia University from 1908 to 1914 and psychotherapy from 1913 to 1918, physician to the U. S. Employees' Compensation Commission from 1920 to 1934, attending urologist and chief, neuropsychopathology clinic, Sydenham Hospital, assistant at the Vanderbilt Clinic from 1908 to 1914 and visiting physician from 1912 to 1918, served during World War I, aged 60, died, April 10, of Parkinson's disease.

William Haymaker Leet, Conneaut, Ohio, Western Reserve University Medical Department, Cleveland, 1895, served during World War I, served as mayor of Conneaut and on the board of education, president of the Citizens' Banking and Savings Company and for thirty-four years president of the Conneaut Creamery Company, on the staff of the Brown Memorial Hospital, a member of the board of trustees of Carnegie Library, a member of the chamber of commerce, aged 72, died, April 22, in Englewood, Fla., of coronary thrombosis.

John L. Adams, Crestview, Fla., Atlanta (Ga.) Medical College, 1914, served during World War I, aged 56, died in April at the Tuberville Hospital, Century.

Joseph Dioscore Bergeron, Negaunee, Mich., Laval University Faculty of Medicine, Quebec, Que., Canada, 1904, also a lawyer, aged 66, died, April 14, of heart disease.

William Richard Brown, Cincinnati, Medical College of Ohio, Cincinnati, 1890, aged 74, died, April 21, of angina pectoris.

Oren Manfred Deems ♂ Springfield, Mass., University of Pennsylvania Department of Medicine, Philadelphia, 1904, served during World War I, on the staff of the Springfield Hospital, aged 63, died, April 11, of cerebral hemorrhage.

John Alexander Dinwoody, Chicago, Trinity Medical College, Toronto, Ont., Canada, 1890, member of the Illinois State Medical Society, medical examiner for merchant marine applicants during World War I, served on the staff of the Jackson Park Hospital, aged 77, died, April 17, of coronary thrombosis.

Louis William Dunavan, San Diego, Calif., Northwestern University Medical School, Chicago, 1892, aged 76, died, April 18, of duodenal hemorrhage.

Harold Webb Garcelon ♂ Auburn, Maine, McGill University Faculty of Medicine, Montreal, Que., Canada, 1908, fellow of the American College of Surgeons, for ten years president of the school board, served on the staff of St. Mary's General Hospital, Lewiston, aged 59, died, April 17, of coronary thrombosis.

Hyman Glanz ♂ New York, Columbia University College of Physicians and Surgeons, New York, 1904, aged 62, died, April 15, of coronary thrombosis.

Harry Goldman ♂ Boston, Tufts College Medical School, Boston, 1918, assistant professor of preventive medicine at his alma mater, deputy health commissioner of Boston, associated with the city health department for more than twenty years, served on the staff of the Beth Israel Hospital, aged 47, died, April 22, of coronary thrombosis.

Henry Philip Graul ♂ St. Louis, St. Louis University School of Medicine, 1905, on the staffs of the Lutheran and St. Anthony's hospitals, aged 62, died, April 16, of heart disease.

Walter P. Grimes ♂ Kansas City, Mo., University Medical College of Kansas City, Mo., 1901, an Affiliate Fellow of the American Medical Association, on the staff of the Menard Hospital, aged 70, died, April 9, of acute coronary occlusion.

Robley Hackett, Churchville, Md., University of Pennsylvania Department of Medicine, Philadelphia, 1892, aged 73, died, April 11, of cerebral hemorrhage.

Meade Eugene Edgar Hagerty, Ferguson, Mo., Baltimore Medical College, 1908, member of the Missouri State Medical Association, served during World War I, served on the staffs of the Missouri Baptist Hospital and the Evangelical Deaconess Home and Hospital, St. Louis, aged 58, died, April 26, of hypertensive heart disease.

Henry Halpert ♂ Scranton, Pa., Bellevue Hospital Medical College, New York, 1895, served on the staff of the Mercy Hospital, aged 70, died, April 18, of coronary thrombosis.

Jerome D. Hamilton, Detroit, Detroit Medical College, 1884, aged 80, died, April 21, of chronic myocarditis.

Edward A. Harper, Columbus, Ohio, Columbus Medical College, 1892, aged 78, was found dead in his home, April 2.

William T. Henry, Springfield, Tenn., University of Tennessee Medical Department, Nashville, 1909, member of the Tennessee State Medical Association, aged 85, died, April 17, in the Robertson County Hospital of coronary heart disease.

Edgar Milne Hewish ♂ Philadelphia, Victoria University Medical Department, Coburg, Ont., Canada, 1883, L.R.C.P., Edinburgh, Scotland, 1883, served as a medical examiner for the draft board during World War I and until recently as a member of draft board number 74, received a testimonial certificate for more than fifty years' medical service from the Medical Society of the State of Pennsylvania, on the staffs of the Lankenau and Jefferson hospitals, aged 84, died, April 11, of chronic nephritis.

James Orville Hill, Huntington, W. Va., University of Louisville (Ky.) Medical Department, 1912, member of the West Virginia State Medical Association, aged 61, died, April 26, in the Memorial Hospital of hypertensive heart disease.

Thomas Jameson ♂ Rochester, N. Y., McGill University Faculty of Medicine, Montreal, Que., Canada, 1892, fellow of the American College of Surgeons, honorary chief surgeon at the Highland Hospital and attending surgeon at St. Mary's Hospital, aged 76, died, April 23, of coronary thrombosis and pernicious anemia.

John J. Janss, Anaheim, Calif., Jefferson Medical College of Philadelphia, 1884, at one time coroner of Martin County, Minn., aged 86, died, April 13, of cerebral thrombosis and arteriosclerosis.

Charles Muntch Johnson of McVeytown, Pa. Jefferson Medical College of Philadelphia 1889, past president of the Mifflin County Medical Society, for many years school medical inspector and physician for the Pennsylvania Railroad, a past president of the staff of Lewistown (Pa.) Hospital, in 1939 received a plaque from the Mifflin County Medical Society for completing fifty years of practice. aged 78, died, April 8 of sarcoma of the upper lip.

Herbert A. Johnson, Palatka Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1902, member of the Florida Medical Association, veteran of the Spanish American War, aged 63, died, April 23, in the Veterans Administration Facility, Lake City, of heart disease.

Josiah Leake, Portsmouth, Va., University College of Medicine, Richmond, 1908, district health officer of Norfolk and Princess Anne counties, aged 62, died, April 17, of cerebral hemorrhage.

Alonzo Chalmers Leslie, Snyder Texas (licensed in Texas under the Act of 1907), aged 82, died, April 1, of heart disease.

Gaylard M. Leslie of Fort Wayne, Ind., Fort Wayne College of Medicine, 1893, for many years president of the Bass Foundry and Machine Company, aged 65, died, April 6, of coronary occlusion.

Edward Augustus Lodge, Milford, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1879, aged 89, died, April 4, in the Pontiac (Mich.) General Hospital of bronchopneumonia.

Henry Christian Lovis, South Orange, N. J., College of Physicians and Surgeons, New York, 1893, member of the Medical Society of the State of New York, also a pharmacist, aged 72, died, April 3.

William Tappan Lum, Alameda, Calif., Syracuse University College of Medicine, 1895, served on the city board of health and the board of education, colonel in the medical reserve corps of the U. S. Army, not on active duty, served during World War I, aged 73, died, April 7 in the Alameda Hospital of bronchopneumonia and myocarditis.

Henry Martin McGehee, Talbotton, Ga., Emory University School of Medicine, Atlanta, 1916, aged 50, died, April 10 in a hospital at Atlanta.

Harry Oren Maldiner of North Tonawanda, N. Y., University of Buffalo School of Medicine, 1914, member of the Radiological Society of North America, Inc., on the staff of the De Graff Memorial Hospital, aged 55, died in April of coronary disease.

Charles Markwell, Versailles, Ky., Hospital College of Medicine, Louisville, 1892, aged 75, died, April 8 in the Eastern State Hospital, Lexington, of perforated gastric ulcer.

John Masselink, Zeeland, Mich., Detroit College of Medicine, 1904, aged 65, died, April 2, in the Holland (Mich.) City Hospital of cerebral hemorrhage.

David Henry Mendelsohn of Paterson, N. J., Jefferson Medical College of Philadelphia, 1910, fellow of the American College of Surgeons, attending surgeon, Nathan and Miriam Barnett Memorial Hospital, aged 55, died, April 7 in Miami Beach, Fla., of heart disease.

John O'Brien Jr., Hampton, Va., Medical College of Virginia, Richmond, 1901, served in France and with the 76th division of the American Expeditionary Forces during World War I, aged 66, died, April 2 in the Veterans Administration Facility, Kecoughton, of coronary arteriosclerosis.

Frank William Pilliod, Toledo, Ohio, St. Louis University School of Medicine, 1915, member of the Ohio State Medical Association, served overseas as a captain in the medical corps of the U. S. Army during World War I for twenty years physician to the Ursuline Convent, aged 52, on the staff of St. Vincent's Hospital, where he died, April 11 of endocarditis.

George Joseph Pomainville of Nekoosa, Wis., Wisconsin College of Physicians and Surgeons, Milwaukee, 1904, past president of the Wood County Medical Society, served as mayor of Nekoosa, health officer of Nekoosa and Port Edwards on the staff of the Riverview Hospital, Wisconsin Rapids, aged 62, died, April 10, of lymphosarcoma of the jejunum.

Elmer Tower Prizer of Lancaster, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1896, past president of the Lancaster County Medical Society, chief of the department of gynecology and obstetrics and vice president of the medical staff at St. Joseph's Hospital, where he took an active part in organizing the training school for nurses, a

director of the former Peoples Trust Company and later of the Farmers Trust Company, aged 75, died, April 12, in the Hahnemann Hospital, Philadelphia, of carcinoma.

Elwood Isaac Rogers, Ridgefield, Conn., Atlantic Medical College, Baltimore, 1910, aged 65, was killed, April 1, in an automobile accident.

Donald William Schafer of Fort Wayne, Ind., University of Cincinnati College of Medicine, 1923, served during World War I, recently an examining physician for the Allen County Selective Service System, on the staff of St. Joseph Hospital, aged 48, died, April 12, of coronary occlusion.

Walter William Schmid of Charleroi, Pa., University of Pittsburgh School of Medicine, 1916, served during World War I, member and secretary of the senior surgical staff of the Charleroi Monessen Hospital, aged 56, died, April 9, of hypertensive heart disease.

Alvin Hiram Sippy, Clayton, Mo., Missouri Medical College, St. Louis, 1885, aged 79, died, April 13, of arteriosclerosis.

Arthur Howard Smith of Marietta, Ohio, Medical College of Ohio, Cincinnati, 1898, served as a major in the medical corps of the U. S. Army during World War I, for many years physician and surgeon for the Baltimore and Ohio Railroad on the staff of the Marietta Memorial Hospital, aged 70, died, April 7, of cerebral thrombosis and heart disease.

John Soterios Soteropoulos, Kansas City, Mo., National University of Athens School of Medicine, Greece, 1904, aged 60, died, April 18, of acute coronary occlusion.

John Madeira Spetnagel, New York, University and Bellevue Hospital Medical College, New York, 1901, aged 68, died, April 8 in St. Luke's Hospital of cirrhosis of the liver.

William Cromwell Stone, Greenville, S. C., Medical College of the State of South Carolina, Charleston, 1913, served during World War I, aged 59, died, April 5, in the Veterans Administration Facility, Atlanta, Ga., of bronchopneumonia, diabetes mellitus and paraplegia of the lower extremities.

Frank Wesley Sweetland of Angola, N. Y., University of Buffalo School of Medicine, 1878, for many years mayor, member and president of the board of education of Angola, aged 87, died, April 13, of acute urcemia, chronic nephritis and arteriosclerosis.

Jesse Adolphus Work, Blue Creek, W. Va. (licensed in West Virginia in 1898), aged 73, died, April 8.

DIED WHILE IN MILITARY SERVICE

James Philip Citta, Toms River, N. J., Jefferson Medical College of Philadelphia, 1937, diplomate of the National Board of Medical Examiners, member of the staff of the Royal Pines Hospital, Pinewald, major in the medical reserve corps of the U. S. Army, flight surgeon stationed at Shawfield, S. C., was killed in an airplane accident near Roanoke, Va., May 15, aged 31.

Henry Hill Connolly, Brookline, Mass., Tufts College Medical School, Boston, 1941, lieutenant, junior grade, medical corps of the U. S. Naval Reserve, aged 27, died, January 5, in the U. S. Naval Hospital, Chelsea, of meningococcal meningitis.

Jacob J. Horwitz of Milwaukee, Rush Medical College, Chicago, 1919, specialist certified by the American Board of Obstetrics and Gynecology, Inc., formerly clinical instructor in obstetrics and gynecology at the Marquette University School of Medicine, attending gynecologist and obstetrician to the Mount Sinai Hospital, major medical corps, Army of the United States, aged 49, died, April 24, at Hot Springs National Park, Ark., of exsanguination following incision of the wrists, self-inflicted.

Abe A. Hyman, Chicago, Loyola University School of Medicine, Chicago, 1938, member of the Illinois State Medical Society, first lieutenant in the medical corps of the Army of the United States, aged 33, was killed, May 17, when a truck in which he was riding overturned near Dermott, Ark.

Stuart Terry, Pontiac, Mich., University of Michigan Medical School, Ann Arbor, 1933, member of the Michigan State Medical Society, lieutenant in the medical corps of the U. S. Naval Reserve, aged 35, was accidentally drowned in New Zealand, Dec. 20, 1942.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Armit Mineral Water—This was reported by the Federal Trade Commission to consist of city tap water supplemented by certain minerals in small quantities and by a relatively larger amount of sodium sulfate, through which mixture has been conducted a current of electricity. In October 1942, one Ralph R. Markwood trading as Armit Mineral Water Company, Toledo, Ohio, signed a stipulation with the Federal Trade Commission agreeing to discontinue the following misrepresentations for his product: that the treatment of the water by electrolysis imparts therapeutic value to it; that the water is effective in replenishing an impoverished blood stream, overcoming congestion in the intestinal tract, preventing or correcting the accumulation of toxins in the system or invigorating every organ and cell of the body; that the preparation when taken as directed will constitute a competent treatment or dependable relief for a long list of ailments including rheumatism, appendicitis, arthritis, asthma, common colds, diabetes, gallstones and heart, liver and kidney disorders; or that it has any effect on constipation other than by affording temporary relief such as any saline laxative would produce. Markwood further agreed to discontinue use of such statements as "scientifically balanced artificial mineral water" to imply that the mineral content of the water is of such kind, quantity and proportion as to supply the bodily requirements of minerals in adequate and correct proportion when the preparation is taken as directed.

Bathritis—In October 1942 one James P. Galligan, trading as Bathritis Company, Chicago stipulated with the Federal Trade Commission that he would discontinue the following misrepresentations in his advertising of his product: that when used as directed in the bath it would have any therapeutic effect in the treatment of rheumatism, neuralgia or other ailments; or when applied as a liniment would be effective in excess of relieving pain; that it relieves sprains, stiffness and swelling; or works toward restoring normal active muscular health; that it is effective in comforting, inflamed tissues and dispelling body odors; or is a new discovery.

Delano's—In October 1942 F. H. Delano and the Delano Company, Inc., of Syracuse, N. Y. signed a stipulation with the Federal Trade Commission in which they agreed to cease representing their product as a remedy or cure for rheumatism and as a tonic or alterative. Further, they agreed to discontinue any advertising which represented that their preparation or any other of substantially the same composition, whether sold under the name "Delano's" or any other trade style, is safe and harmless, or any advertisement which failed to reveal that the product should not be used when abdominal pains, nausea, vomiting or other symptoms of appendicitis are present; that its regular or continued use might result in dependence on laxatives or that the administration of the mixture regularly or over a considerable period of time unsupervised by a physician may result in injury to the user. It was provided, however, that such advertisements need contain only the statement "Caution: Use only as directed," when the label itself contains sufficient warning.

Dulse Dene Vita Broth, Garlo-Min, Vege Molen Vita Lax and M 7—These were the subjects of a stipulation which one Andre Tempe, trading as Master Vita Mini Laboratories, Chicago signed with the Federal Trade Commission in October 1942. In this he agreed to discontinue the following misrepresentations in the advertising: that only organic compounds of iodine preparations are nutritionally effective; that the administration of iodine preparations will increase immunity to disease; or that the use of such a product in combination with vitamin A will improve vitality; or that his product, "Dulse Dene," is an adequate treatment for nervousness or arthritis; or produces vitality in general or remarkable results in school children; that the American dietary is deficient in minerals; that it is impossible to obtain adequate nourishment from the customary articles of diet; or that it is impossible to obtain sufficient minerals from various vegetables unless they have been subjected to a special treatment such as is used in preparing the vegetables contained in Tempe's product, "Vita Broth"; that "Garlo Min," because of its dried garlic or other content, has any therapeutic effect in treatment of high blood pressure, or prevents disease and promotes good health; or that the use of garlic promotes longevity; detoxifies the colon; soothes the nervous system; or has a favorable influence on arteriosclerosis or high blood pressure; that either okra or the respondent's product, "Vege Molen," is an effective treatment for stomach ulcers, duodenal ulcers, colitis, chronic constipation, hemorrhoids or acid stomach; or that cancer generally results from colon irritation; that "Vita Lax" prevents hyperacidity, toxemia or intestinal putrefaction; or is free from drugs and is not habit forming; that

vitamin A can be depended on as "anti-infective" to promote healthy skin and normal eyesight and build resistance against colds and infections; that vitamin B overcomes nervousness and irritability; that vitamin C maintains health of teeth and gums; that vitamin E promotes muscular normalcy and vigor to help prevent anemia; that vitamin G is a natural promoter of clear skin; or that the respondent's product "M 7," by reason of its vitamin or other content, constitutes a competent treatment for such diseases, symptoms or conditions. The concern further agreed to discontinue the use of the term "vitamin F" to describe the content of any of its preparations, or otherwise to designate any ingredient by a purported scientific name or term not recognized by the prevailing weight of authorities in such field of science.

Products of Allied Pharmaceutical Company, Inc., Cleveland—This concern also operated as Erie Laboratories, Inc., Avon Pharmaceutical Company, Victor Drug Products, Mason Pharmaceutical Company, Mack Pharmaceutical Company, Dale Drug Products and Murray's. In October 1942 the Federal Trade Commission accepted from the concern in question a stipulation agreeing to discontinue using or supplying to others for their use, advertising matter making the following misrepresentations for their products: "Lee's O B Tablets" (also sold under the name "Lee's Obesity Tablets") permanently reduces weight and increases vitality; "Quits" (also sold as "Chicks," "Halls" and "Braks") overcomes the liquor habit and is tasteless and harmless; "Murray's Procon Tablets" (also known as "Dale Urotone Tablets," "RLD Procon Tablets," "Hite's Inco Tablets" and "Mack's Inco Tablets") removes excess acid, neutralizes waste matter and has value in treating prostatic troubles or conditions secondary to or associated with prostatic or urinary disorders; "Elco Hepo (Hepatic) Tablets" (also sold under the names "Murray's Hepo Tablets" and "Hite's Okay Hepo Tablets") corrects habitual constipation, jaundice or gallstones or overcomes the cause of constipation, headaches, dizziness, marred complexion or poor eyesight; "Hay Fever and Asthma Preparation" is a remedy or cure for hay fever, asthma, sinus or summer colds or affords anything but temporary relief from symptoms of such disorders; "L. H. C. Lee's Herbal Compound" restores strength or vigor to persons suffering from nervousness or rundown condition because of overwork, excessive eating, or too strenuous living; "Elco Iocin Tablets" (also sold as "Dale's Salicoid Tablets," "Grabill's Tablets" and "Hart's Tablets") is a competent treatment or cure for rheumatism, arthritis, lumbago, neuralgia or swollen joints or affords more than temporary or partial relief from muscular pains and aches caused by such disorders; "Furnas" (also known as "Mack's Moxel") corrects stomach disorders generally and gives relief from distress resulting from loss of appetite, sleeplessness and dizziness when not due to constipation; "Elco Evora Salve and Liquid" (known also as "Murray's Evora" and "Mack's E. Z.") is a remedy or cure for skin diseases or will clear up disfiguring skin conditions. The respondent corporation further stipulated that it would discontinue any advertisements of Quits, Elco Iocin Tablets, Furnas or Hay Fever and Asthma Preparation or any other products of substantially the same ingredients or properties as these, the use of which is patentable, dangerous to health and the advertising of which fails to reveal such potential danger. It was provided, however, that if the directions for use of these preparations, whether on the label or in the labeling, contain an adequate warning of the potential danger to health such advertising need carry only the statement "Caution: Use only as directed."

Taylor's Kolnox Compound—Roy E. Phipps, trading as Taylor Drug Company and Taylor Drug and Seed Company, Bessemer, Ala., stipulated with the Federal Trade Commission in October 1942 that he would discontinue the following misrepresentations for his product: that it will help the system maintain proper alkaline balance; that it is a cold remedy and will prevent, fight, control or rid one of colds; that it will clear the system of poisons, relieve bad coughs, or have any value with respect thereto, beyond its ability to exert a slight cooling effect on the throat; or that it will relieve or ease congestion. Phipps further agreed to discontinue representing that his product is safe to use in all cases and to discontinue any advertisements which failed to reveal that the preparation should not be used when symptoms of appendicitis are present. He was permitted, however, to limit this warning in the advertising to the brief statement "Caution: Use only as directed," provided the directions wherever they might appear, contain adequate warning to the same effect.

Vi Co Compound—The promoters of this, Irving Z. Harris and Pauline B. Harris, trading as Velux Company and Vi Co Sales Company, North Birmingham, Ala., signed a stipulation with the Federal Trade Commission in August 1942 in which they agreed to discontinue the following misrepresentations: that this product is a vegetable and mineral compound; that it will afford relief from indigestion and sour stomach; and that in future advertising they will cease using the word "tonic" either alone or with other words to describe the preparation.

Vivi Ta Superior Wheat Germ—This is put out by Claire L. and Emil J. Specht, doing business as Vegetable Juice and Products Company and Vegetable Products Company, Rochester, N. Y. For a time the respondent represented that this product would provide users with vitamin A and the minerals calcium, iron, copper, magnesium and manganese; that it could be relied on to prevent colitis, sterility, eye cataracts, gray hair or successfully treat catarrh, arthritis, neuritis, eczema, anemia, stimulate the liver and pancreas, strengthen the heart muscle, retard old age, normalize calcium metabolism, improve the condition of the sinus membranes or of the hair, nails or scalp, increase energy, vigor, mental powers, nerve and muscle tone, provide effective aid during the menopause, exert a specific nourishing effect on the nerves and brain, favorably affect cases of constipation arising from lack of energy and revitalize tissues and glands. These claims are being discontinued, according to a stipulation which the Spechts signed with the Federal Trade Commission in October 1942 in which they agreed that the claims should not be repeated except when and to the extent that the disorders named may be due to a deficiency of the vitamins which the product furnishes.

MEDICAL EDUCATION AT THE FRONT

To the Editor—About six weeks ago I requested a subscription be sent to me of THE JOURNAL. Communications are, of course, a bit uncertain across the sea lines these days, and so I thought I would send a V mail inquiry as to whether you received my request.

Incidentally, I might say that the reason I've asked for the subscription is so I could keep the copies longer. For in this particular section of the service—under bomber command—the various medical officers in this wing are sent at periodic intervals copies not only of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION but also of the British journals—like the *Lancet* and the *British Medical Journal*. Lieut Col A L. Streeter the wing surgeon has been quite attentive to details of this sort and has constantly sought to keep up the medical interest of his staff.

Medical officers in this wing are always encouraged to attend the weekly medical meetings held at Second Evacuation Hospital—staffed by the St. Luke's (New York) unit. At the last meeting held May 21, the chief of the surgical service there, Lieut Col MacFee, introduced Col Rev L. Dively who presented a kodachrome film on amputations. Colonel Dively also introduced Dr. Freyberg from Sweden who was visiting England the previous three weeks at the request of the Swedish ministry of health. Professor Freyberg, a very mild mannered soft spoken blue eyed Nordic spoke of the present situation in neutral Sweden and talked at some length on the status of medicine in that country. According to the professor, the surgeon in Sweden must work for the government gets a salary rarely exceeding \$2000 does not become a chief of surgery in a hospital until he is over 40 and has but little opportunity for outside practice. Other interesting personalities in the field of medicine that have spoken at the weekly medical meetings at the Second Evacuation Hospital in the past ten months are Col William S. Middleton from the University of Wisconsin Medical School, Lieut Col Theodore L. Badger chest specialist from Boston, and the neurosurgeon Capt. Arthur Ecker, who spoke on the topic of low back pain.

The medical side of this war is doing well.

'SMALLPOX VACCINATION REACTIONS'

To the Editor—I have read with great interest the communication on the subject 'Smallpox Vaccination Reactions' (THE JOURNAL, June 5 p. 395). The loss of immunity to smallpox takes place gradually and is subject to considerable individual variation. In my experience beginning vaccinoïd reactions occasionally showed as early as the second day.

For the past two years I have promoted smallpox revaccination by emphasizing the fact that it should be regarded in the same light as the Schick test for susceptibility to diphtheria which has the added advantage of not requiring any further procedure to remedy the lack of protection, if immunity to smallpox is not present. I heartily second the proposal to attach Jenner's name to the immune reaction. However I should like to suggest that the appellation 'Jenner test' would be more appropriate in stressing its value as a routine public health measure as well as its importance in determining the immunity of contacts to a case of smallpox.

USE OF SULFATHIAZOLE LOCALLY IN OTOLARYNGOLOGY

To the Editor—The editorial comment regarding the use of sulfathiazole locally in the nose, pharynx and larynx (THE JOURNAL, May 15 p. 180) prompts me to suggest that a word of caution is in order. In the course of certain experiments that we were carrying out it became desirable to test the capillary network of the lung as an absorptive surface for drug administration. This was done first by using atomized mists from suspensions of various sulfonamides, with resulting high blood levels of the drug (Harris T N, Sommer, Harriet E, and Chapple C C. *Am J M Sc* 205 1 [Jan] 1943).

Certain disadvantages of the mists prompted the trial of dry sulfonamide powders as smokes from specially designed, though very simple blowers. This work is being reported in the *American Journal of the Medical Sciences* in detail, but one of the results should be mentioned here namely that three deep breaths in the adult taken while the smoke is being blown through the nose and/or mouth produce a sulfonamide blood level of 3 to 5 mg per hundred cubic centimeters of blood in less than fifteen minutes as measured at the finger tip. This level rises for some hours to approximately double the original figures and at the end of two days is usually still above 1 mg per hundred cubic centimeters. As the smoke contains very much less drug than the quantities mentioned in the editorial comment it would seem that some cognizance should be taken of this fact.

Philadelphia

TRAUMATIC WINGED SCAPULA

To the Editor—In the February 27 issue of THE JOURNAL appears a clinical note entitled 'Two Additional Cases of Traumatic Winged Scapula Occurring in the Armed Forces,' by Majors Charles U. Hauser and William F. Martin of the Medical Corps, Army of the United States. Two reasons prompt this immediate note for publication in THE JOURNAL.

1 The authors are inconsistent in their method of avoiding stretching of the paralyzed serratus magnus muscle and of its antagonists and in the prevention of contractures in their antagonists for in their first case they employ a most improper and inefficient mechanical measure the sling while in their second case they utilize the accurate principle of upward pressure beneath the flexed elbow with the arm adducted to the side.

2 The authors in discussing their use of the second method make the noncommittal statement 'We make no claims for originality in presenting the detailed pictures of a simple and expedient immobilization cast.' If the authors had reviewed the literature they would have found this method described for the first time by Tocantins and myself in the *Journal of Bone and Joint Surgery* in 1938. The efficient apparatus that we employed consisted of a pelvic celluloid base with an adjustable celluloid cup to force the elbow on the affected side upward.

EFFECT OF pH ON ACRIDINE COMPOUNDS

To the Editor—In the May 8 issue of THE JOURNAL page 117 I note in the editorial describing the acridine compounds the statement 'As early as 1913 Browning and Gilmour demonstrated that the action of the diaminoacridine compounds in contrast to all other efficient antiseptics is intensified rather than reduced when the medium contains serum.' More recent work has shown that it is not the serum which influences this intensification but the change of the pH of the medium.

CONTINUATION COURSES FOR
PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning continuation courses for practicing physicians available in the various centers is published quarterly. The following list con-

sists of courses beginning during the period July 1, 1943 Sept 30, 1943. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer.

VICTOR JOHNSON, M D
Secretary, Council on Medical
Education and Hospitals

Continuation Courses for Practicing Physicians—July 1, 1943–Sept 30, 1943

Institution	Schedule of Course	Title of Course	Number of Students Accepted	Registration Fee and/or Tuition
ALLERGY—See also Dermatology & Syphilology				
Harvard Medical School, 25 Shattuck Street, Boston, Mass. Write to Dr. Frank R. Ober, Assistant Dean, Courses for Graduates	July 7 to 2 weeks, part time	Clinical Allergy	6 ¹	\$20
University of Pennsylvania Graduate School of Medicine, 237 Medical Laboratories, Philadelphia, Pa. Write to Dr. R. C. Burkli, Dean, The Medical-Chirurgical College	Arranged 4 weeks, about 10 hours	Allergy	Individuals ²	\$1.00
Dr. Vaughn and Graham, 201 West Franklin Street, Richmond, Virginia. Write to Dr. Warren T. Vaughn	1 year course Every 6 months	Training in Allergy	Limited	.
ANATOMY—See also Otolaryngology Surgery				
Harvard Medical School, 25 Shattuck Street, Boston, Mass. Write to Dr. Frank R. Ober, Assistant Dean, Courses for Graduates	July Aug. - 6 weeks	Microscopic Anatomy	Limited ¹¹	\$20.00
New York Medical College, Flower and Fifth Avenue Hospitals, 5th Avenue at 105th Street, New York City. Write to Dr. J. A. W. Hetrick, Dean	Arranged 160 hours	Applied Anatomy of Pelvis and Abdomen		\$20
ANESTHESIOLOGY				
Columbia University, Faculty of Medicine, at the New York Postgraduate Medical School, 305 East 20th Street, New York City. Write to Director of the School	Continuously 2 weeks Arranged 12 sessions	Anesthesia	12	\$100, \$20 for 1st week ¹¹
Harvard Medical School, 25 Shattuck Street, Boston, Mass. Write to Dr. Frank R. Ober, Assistant Dean, Courses for Graduates		Regional Anesthesia	2-4	\$15.00

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Federal Food, Drug and Cosmetic Act Marmola Tablets for Obesity Misbranded—The United States filed a libel in the federal district court, western district, Wisconsin, for the condemnation of a shipment in interstate commerce of Marmola Prescription Tablets, marketed as a cure for obesity, on the grounds that the preparation was misbranded within the meaning of the Federal Food, Drug and Cosmetic Act. The Raladani Company, hereinafter referred to as the claimant, which marketed the preparation to wholesale and retail outlets, intervened in the proceeding, denied the allegations of the libel and contended that the provisions of the Federal Food, Drug and Cosmetic Act relied on by the government were unconstitutional.

The district court first disposed of the claimant's contention that the provisions of the Federal Food, Drug and Cosmetic Act relied on by the government were unconstitutional. That act, said the court, was designed to regulate commerce in food, drugs and cosmetics and to protect the public against foods and drugs that are dangerous to health as well as those which are falsely branded. It is well settled that Congress has the power, under the commerce clause of the Federal Constitution, to condemn the interstate transportation of misbranded drugs and to make such articles contraband when so transported. Section 502 of the act [21 U. S. C. A. 352] provides that a drug or device shall be deemed to be misbranded "(a) if its labeling is

false or misleading in any particular dangerous to health when used in the dosage, or with the frequency or duration prescribed, recommended, or suggested in the labeling thereof." Subsection n, section 201 of the act [21 U. S. C. A. 321], provides that in determining whether the labeling of an article is misleading there shall be taken into account, among other things, not only representations made or suggested by statements, words, designs, devices or any combination thereof but also the extent to which the labeling fails to reveal facts material in the light of such representations or material with respect to consequences which may result from the use of the article to which the labeling relates under the conditions of use prescribed in the labeling. There is no constitutional objection to any of these sections. There was no unlawful delegation of legislative power by Congress, nor do the acts of the government pursuant to the provisions of the statute constitute an exercise of legislative power in violation of the constitution. Congress has set up in the act its own policies and standards, and the act and the sections thereof involved in these proceedings are well within the powers of Congress to enact.

The libel alleged that the preparation was misbranded within the meaning of the three sections of the act mentioned because (1) it was dangerous to health when used in the dosage or with the frequency prescribed in its labeling and (2) the labeling was false and misleading by reason of its failure to reveal facts with respect to consequences which may result from its use under the conditions of use prescribed on the label. The claimant denied these allegations. There was present in each tablet of the preparation $\frac{1}{2}$ gram (0.03 Gm) of desiccated thyroid, containing approximately 0.3 per cent organic iodine which is about 50 per cent more organic iodine than is present in desiccated thyroid U. S. P., producing consequently greater physiologic effect than equivalent amounts of a U. S. P. product of desiccated thyroid. It was the failure of the label adequately to conform to the provisions of the act previously discussed because of the presence of the desiccated thyroid in the preparation that formed the real basis of the government's libel. According to the labeling of the preparation, it is intended as a cure for obesity and is for use only by obese persons who are otherwise normal and healthy and whose obesity is caused by hypothyroidism with accompanying subnormal metabolism. The labeling further represents that hypothyroidism is the basic cause of obesity, which results from a lack of a substance which Marmola supplies, and recommends a dosage, where indicated of 4 tablets daily. This daily dosage recommended, the court observed, is equivalent to 2 grains (0.13 Gm) of desiccated thyroid containing 0.3 per cent organic iodine, or to 3 grains (0.2 Gm) of desiccated thyroid containing 0.2 per cent organic iodine in a U. S. P. product. The court then went on to discuss the reasons why the preparation if marketed as labeled was potentially dangerous.

The preparation, said the court, is offered to the public as a treatment for obesity, which was defined by the expert witnesses in the case as an excessive development or excessive storage of fat throughout the body. Those witnesses differed in their opinions as to the cause of obesity and its cure. Some believed that overweight is caused by excessive eating and lack of proper exercise and that the weight may be reduced by dietary measures coupled with adequate exercise. Some witnesses called by the claimant believed that most obesity is caused by endocrine disturbances or disorders, that the thyroid gland is the regulator of the metabolic processes and that obesity is due at least in a large part to the deficient activity in this gland and hence that in its treatment thyroid medication is indicated. Other witnesses believed that obesity is caused both by overeating and by endocrine disturbance. To determine the significance of the objectionable labeling in the light of the expert testimony, the court then found it necessary to discuss hypothyroidism and metabolism. Hypothyroidism, said the court, is the underfunctioning of the thyroid gland which is a condition of disease, and is accompanied by a subnormal

[or] (j) if it is

basal metabolic rate and by other symptoms such as dryness of the skin, sparseness of hair and eyebrows, sluggishness of physical and mental reactions, decreased appetite, slower pulse rate and characteristic changes in the composition of the blood and in advanced stages of hypothyroidism or myxedema, hypofunction and swollen appearance of the face and other parts of the body due to a collection of mucoid fluid beneath the skin. Metabolism is the total of the various processes by which food is transformed in the body into the chemicals which are absorbed in the blood stream and lymphatic system to nourish and build up or repair the body and by which tissues are destroyed and waste matter is excreted. The health of the body depends on the well balanced use of the body chemicals. The rate of metabolism is measured by the rate at which the body produces or gives off heat. The basal metabolic rate is the lowest rate of chemical activity that will maintain the absolutely essential functions of the body sufficiently to keep an individual alive. Every activity of the body increases the amount of energy consumed. Having ascertained the basal requirements of a person a physician can by the addition of the demands of that person's other activities compute what his total needs will be. Average normal standard rates have been established but normal healthy persons may vary from the average standard normal rate from 10 per cent to 15 per cent more or less than standard. Desiccated thyroid is used in the treatment of hypothyroidism and the optimum daily dosage in such treatment must be determined for each individual case as it varies with each individual and is established only by trial and error. That optimum may be as little as $\frac{1}{4}$ grain (0.016 Gm.) a day and in most cases less than 2 grains a day although there are some cases in which dosage exceeds 2 grains a day depending on the under functioning of the individual's thyroid gland. The labeling on Marmola however it will be recalled prescribes in all events and for all individuals of what would be equivalent to 3 grains daily of a U S P product.

There was a substantial agreement continued the court among the medical witnesses concerning the following facts: The overdosage of desiccated thyroid results in an increase in the metabolism of the person taking it and has a toxic effect on hypothyroid persons in that it increases their basal metabolic rate and injuriously affects the functioning of the endocrine glands, kidney and liver impairing their capacity for normal functioning. Overdosage places an extra burden on the organs of the body and results in symptoms undistinguishable from those disclosed in spontaneous hyperthyroidism such as rapid heart, heart pains, shortness of breath, sleeplessness, nervous and emotional instability, headaches, dizziness, tremor, muscular weakness, disturbances of the alimentary canal, fatigue, nausea and in women menstrual disturbances. The symptoms of hyperthyroidism will disappear days or weeks after the discontinuance of desiccated thyroid but sometimes a more serious and permanent disease and injury to health results. Many persons who consider themselves normal and healthy have been found to have physical impairments or diseases such as impairment of the heart, diabetes or tuberculosis which may be discovered only by a thorough physical examination by an experienced physician. Were such a person to take 2 grains of desiccated thyroid a day the heretofore unknown disease or ailment would be aggravated. In sound medical practice a physician will prescribe thyroid for hypothyroidism only after a careful physical examination is made of the patient's head, eyes, throat, chest, lungs, heart, abdomen and reflexes covering the nervous system to ascertain whether the patient is suffering from any latent or underlying disease of which he is unaware such as diabetes, tuberculosis or heart ailment. In some instances a basal metabolism is done, roentgenograms of the chest are made and an electrocardiogram of the heart is obtained. Any drug the court emphasized which for safety in its use requires diagnosis and evaluation and when taken in the dosage and with the frequency recommended and suggested in its labeling may expose the users to disease and pain is dangerous to health. Marmola is such a drug. In it there is

an inherent and potential danger that may reasonably be expected to attend its use when one considers that it will be used by the strong, the weak, the old, the young, the well and the sick without first having a physical examination or a diagnosis made by a competent physician.

Obesity continued the court is not caused by hypothyroidism as is suggested in Marmola's labeling. Those suffering from hypothyroidism are sometimes overweight owing to the deposit in the body of a mucoid substance which is not fat and which desiccated thyroid may remove under proper treatment. Desiccated thyroid may stimulate the appetite and its use may result in increased weight unless the dosage is so large as to result in hyperthyroidism which is a disease. Obesity is not affected materially by the use of Marmola prescription tablets as prescribed or by desiccated thyroid of comparable daily dosages except by producing and maintaining a condition of hyperthyroidism. The discontinuance of Marmola on the appearance of unpleasant effects or unusual circumstances or conditions does not avoid danger. When these effects or conditions appear the user is in a state of hyperthyroidism, which in some cases may result in the precipitation of more serious and permanent injury. A substantial portion of the public, after reading the labeling on the preparation would conclude that obesity is caused by the lack of some substance in the human body which Marmola supplies and that Marmola is a safe and efficient remedy for obesity which is not a fact. The labeling fails to inform the prospective user that if he is suffering from hypothyroidism he is not healthy and normal. It places a duty on the user to make a self diagnosis to determine whether he is suffering from hypothyroidism. The layman lacks familiarity with medical terminology. He has little or no knowledge of medical science and does not possess that skill and learning required to determine whether he is suffering from hypothyroidism. The labeling does not recommend that an obese person considering the use of Marmola should first consult a physician. It does advise that he consult a physician if he desires special advice in any unusual condition or more advice than appears on the label.

The Federal Food Drug and Cosmetic Act said the court was not made for experts nor is it intended to prevent self medication. The purpose of the law is to protect the public, the vast multitude which includes the ignorant, the unthinking, and the credulous who when making a purchase do not stop to analyze. It was enacted to make self medication safer and more effective and to require that drugs moving in interstate commerce be properly labeled so that their use as prescribed may not be dangerous to the health of the user. The court after stating that the administration of thyroid tablets in Marmola dosages is a dangerous procedure and should not be undertaken without a thorough examination by a competent physician was convinced that Marmola when used as prescribed in the labeling was neither a safe, an appropriate nor an efficient remedy for obesity that it was dangerous to the health of the user when used in the dosage or with the frequency and duration prescribed that the labeling is false and misleading in its representations that it is a safe remedy for obesity and in that it fails to reveal facts material with respect to consequences which may result from the use of Marmola under the circumstances prescribed in the labeling. The court held that the product was misbranded within the meaning of the Federal Food Drug and Cosmetic Act. Accordingly it ordered that a decree of condemnation issue—*United States v. 62 Packages More or Less of Marmola Prescription Tablets* 48 F Supp 878 (1943).

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints in a sale are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Glycogen Index in Menopause—Mack reports on the application of the iodine vapor method of staining and the estrogenic response of vaginal smears during the menopause of 130 women and the glycogen response of the smears (as determined by the method) to various commercial estrogens. The method is based on the observation that the normal vaginal glycogen content parallels estrogen sufficiency, whereas diminution of glycogen is indicative of estrogen deficiency. Vaginal smears of 130 climacteric women (after staining by the iodine vapor procedure) were graded according to their glycogen content. Possible "antihormonal" effects of various systemic and local disorders (febrile states and vaginitis) on estrogenic activity are suggested by observation of tuberculous women. The method provides a sensitive index of human estrogenic activity. The persistence of vaginal glycogen in variable amounts in menopausal women provides additional evidence of continued estrogen elaboration by the ovary or extragenital sources. The clinical usefulness of the method is at present limited to the control of estrogen therapy in vaginitis and to the investigation of estrogen potencies in women with advanced menopausal atrophy. Experience with the glycogen index in the human subject permits the following tentative deductions: Theeolol is less effective than an equal weight of theelin. Alpha-dihydrotheelin produces an estrogenic effect comparable to that induced by an equal weight of theelin in oil. Diethylstilbestrol in oil solution produces a more rapid glycogen effect when given by mouth than equal weights of theelin and alpha-dihydrotheelin. The glycogen response to diethylstilbestrol fluctuates widely in comparison to that obtained with theelin and alpha-dihydrotheelin. A theelin-theeolol mixture (0.5 mg of each in oil solution) orally produces a glycogen reaction curve comparable to that induced by 0.5 mg doses of theelin alone. Theelin produces uniform response and maintenance by all routes of administration and can serve as a standard for comparative assays of estrogen in the human subject.

Hemoconcentration and Shock Following Severe Hemorrhage—Weston and his associates caused typical shock to occur in 11 nondehydrated and 15 dehydrated, unanesthetized normal dogs by graded hemorrhage. In 2 of the nondehydrated and 8 of the dehydrated animals hemoconcentration occurred. Determination of the plasma volume and plasma protein, before and after hemorrhage, revealed that in the animals with hemoconcentration additional plasma fluid and protein were actually lost as shock developed. Pathologic changes, consisting of gastrointestinal engorgement and hemorrhage, pulmonary congestion and engorgement and occasional changes in other viscera, were observed in a number of animals. The nondehydrated animals tolerated an average total blood loss of 49 per cent as compared to the 43 per cent tolerated by the other animals. The changes in plasma protein concentration after hemorrhage indicated that the hemoconcentration in dehydrated animals was hemodiluted during and after hemorrhage to a lesser degree than in the other animals. This relative inability to hemodilute could explain the animals' inability to tolerate as much bleeding before shock and could lessen the magnitude of earlier hemodilution of the subsequent hemoconcentration as shock develops. The conflicting reports on hemoconcentration after hemorrhage may be related to the animals' state of hydration. There are no definite grounds for differentiation between hemorrhagic shock and shock from other causes.

Attitude Toward Immunization Procedures—From the results of a public opinion poll taken in September 1941 among the adult white population in the United States it appears to Baumgartner that: 1 In general the public is aware of the value of immunization against and of the serious nature of diphtheria, smallpox and typhoid and sees no specific drawbacks connected with its being inoculated against them. Therefore public health officials and private physicians should urge the procedure. 2 More than 50 per cent of those who are in need of protection say they might be willing to be protected. 3 The public is not well informed concerning when or how often it is necessary to be immunized. The importance of having children protected against diphtheria and smallpox in infancy needs particular emphasis. 4 Adults responsible for the care of children are generally better informed concerning immunization than other adults.

Butter Fat and Vegetable Oils—The experiments of Hart with young rats indicate that butter fat as compared with certain vegetable oils is superior for their growth. This superiority rests on a constitutional difference and is not related to the differences in the vitamin content. As the sole article of nutrition for infants a filled milk in which a vegetable oil has been substituted for the butter fat, based on rat experiments, could give inferior growth; however no such experiments have been carried out. Until they have been the burden of proof of equal value must rest with the purveyor of filled milk and the public should be protected from a substitute for natural milk.

Demerol as Substitute for Opiates—Rovenshine and Balterman used Demerol as a preanesthetic medication in scopolamine combination for 286 patients and Demerol alone for 52 patients between 15 and 89 years of age. Demerol was given in doses of 50, 75 and 100 mg. and when combined with scopolamine the amounts of the latter were 0.4, 0.5, 0.6 mg. A dose

of 100 mg. of Demerol was used whenever it was thought that the patient would have required 0.016 Gm. ($\frac{1}{4}$ grain) of morphine. Preanesthetic medication was considered satisfactory when the patient at the time of induction was calm and emotionally undisturbed but not depressed to the extent that he would not respond readily to ordinary questions. With the Demerol scopolamine combination regardless of the anesthetic used a satisfactory response was obtained with 100 mg. of Demerol hypodermically in 76 per cent of the 166 patients treated while undue depression was the result in 3 per cent. An equivalent amount of morphine (0.016 Gm.) given to a corresponding number of patients in another service resulted in a satisfactory response in 81 per cent and in deep depression in 9 per cent. Demerol in doses smaller than 100 mg. produced less favorable results except in patients older than 60. A satisfactory preanesthetic state was obtained in 83 per cent of the older patients receiving 75 mg. but this dose was insufficient for 60 per cent of patients between 20 and 60. Three of the 56 patients receiving 75 mg. were too depressed. The 50 mg. dose was likewise unsatisfactory, especially in those less than 60. No individual receiving this amount was too depressed. In 4 aged 63 to 69 the results were satisfactory but more than half of those between 15 and 60 were apprehensive or the drug appeared to have had little or no effect. The optimal time that should elapse after Demerol and scopolamine were administered and before anesthesia was begun was between forty-five and ninety minutes. Demerol appears to provide psychic sedation not surpassed by morphine, it does not depress respiration or other vital functions to the same degree as morphine does. It facilitates the induction of anesthesia as does morphine, it is more effective in drying secretions than morphine, it has fewer unfavorable side effects and it reduces the usual amount of anesthetic agent required for an optimal narcosis.

Continuous Caudal Analgesia—Since October 1941 Hingson and Edwards have used continuous caudal analgesia in 250 surgical gynecologic and urologic procedures and in 600 deliveries. The advantages of the method are ease of administration, accurate control, safety to the mother and the child, freedom from pain during labor or after operation, expedited labor, reduction of the third stage complications and the complications of the puerperium and the indications that such a regimen would facilitate the handling of wartime injuries with considerable and prolonged relief of pain for the injured. The method should be studied in the large recognized obstetric clinics by especially trained physicians before a final appraisal of its merits is given. It is not a procedure to be experimented with in an occasional case. The utmost cooperation must exist between the experienced physician anesthetist and the obstetrician in the handling of a patient so anesthetized. The problem of securing equipment through the wartime rationing is being given serious consideration. Substitute apparatus, especially with regard to needles, should not be encouraged.

- *Palindromic Rheumatism in Allergic Persons W. F. Vaughn—p. 256

Palindromic Rheumatism in Allergic Persons—Vaughn determined the incidence of arthritis in 1000 consecutive adults with asthma, hay fever, urticaria, angioneurotic edema, migraine, gastrointestinal allergy or allergic dermatitis. Of the total, 382 were males and 618 females, 206 (20 per cent) complained or had complained of rheumatic pains. All but 6 received careful physical examination including the joints. Of the 200 so studied 90 presented some evidence of articular pathologic changes. Of the 90 with recognizable articular changes, 9 were classified as rheumatoid or atrophic and were characterized especially by swelling of the proximal joints of the fingers, 32 were classified as hypertrophic or osteoarthritic as characterized by nodal enlargement of the terminal joints of the fingers and velvety or sandpaper crepitation of the knee joints, 29 were classified as combined arthritis and in 18 the involvement was limited to large joints other than the knees, in 2 the condition was traumatic. Of the 206, 64 were males and 142 females and of the 90 with articular changes 25 were males and 65 females. Of the 206, 143 had allergic symptoms attributable to food, 48 inhalant allergy and 15 had only contact dermatitis. The incidence of food allergy was 69 per cent in the 206 with rheumatic history, and the 90 with articular changes and the remaining 31 per cent had no important food allergy. The allergy in 55 per cent of 749 allergic persons without rheumatic complaints was due to food. The foods mentioned as rheumatic offenders did not include the conventional hearsay foods usually suspected in rheumatism.

Desoxycorticosterone Acetate and Peripheral Vascular Diseases—Sirota states that the beneficial physiologic effect of hypertonic solution of sodium chloride intravenously in thromboangitis obliterans and arteriosclerosis obliterans can

within limits be attained by the intramuscular injection of desoxycorticosterone acetate, which also often appears to lower the blood pressure, more often it may cause an increase in the local cutaneous temperature and occasionally an increase in oscillometric readings. A permanent lowering of the blood pressure was not obtained, rest also was a contributing factor in these cases. The encouraging results in 20 cases appear to warrant more extensive clinical study. Desoxycorticosterone acetate cannot be regarded as a substitute for intravenous saline therapy, but it may serve as an excellent adjuvant. It is useful when an intravenous technique or sudden increases in blood volume are contraindicated.

Infertility in Male and Vitamin Therapy—According to Biskind and Falk, nutritional therapy, especially with the vitamin B complex, alone or in combination with vitamin E, improved the number, motility and morphology of the sperm of previously infertile men. In others with sterility whose initial specimens of spermatic fluid were apparently normal, therapy with vitamin B complex alone apparently restored fertility without the production of any significant detectable changes in the sperm. Excluding one man among twelve with virtual azoospermia who were so treated, eight impregnations occurred. The wife of one of these patients aborted at the fourth month, but the others are approaching term or have been delivered of normal babies.

Treatment of Menstrual Disturbances in Adolescent Girls—The vaginal smears of 7 girls from 11 to 15 years of age who complained of severe and/or prolonged menstrual bleeding were studied by Rubenstein. On the basis of the cell types he separated the cases into two groups, one to be treated with estrogen and the other with progesterone. The bleeding of all patients was successfully controlled by the appropriate therapy.

- *Nonspecific Factors in Resistance: VI. Incidence of Common Cold in Persons With and Without Accessory Symptomatology of Nonreaginic Food Allergy W. B. Brown, Irma Graham, Ariel Niedringhaus and A. Locke, Pittsburgh—p. 101

Individual Specificity of Human Serum—According to Cumley and Irwin, following the absorption of precipitins in antihuman serum produced in rabbits, the reactions that were obtained with the serums of different persons led to the conclusion that the serum of human beings contains antigenic components by which the serum of one individual can be distinguished from that of another.

Nonspecific Factors in Resistance—A study is reported by Brown and his co-workers which extends the evidence recently reported by Coca for the existence of a cause and effect relationship between the presence of nonreaginic food allergy and the predisposition to the common cold. Two or more of Coca's eleven symptomatic evidences (urticaria, indigestion, abdominal pain, constipation, headache, canker sores, dizziness, tiredness, nervousness, neuralgia and sinusitis) of the presence of nonreaginic food allergy were present in 79 per cent of 422 college girls. Each of the symptoms, when present, was associated on the average with a higher incidence of colds than observed in their absence. There was a progressively increasing incidence of colds when the number of symptoms increased.

There was no correlation between the presence of symptoms and poor condition based on the performance of a modified Flick test. The handicap of poor condition was however reflected in a heightened cold incidence, as was the handicap of addiction to smoking. The girls with the greatest total handicap from all sources, had roughly four times as many colds as those with the least.

Sterility Test for Sulfanilamide Powders M. Lands and Elizabeth J. Oswald—p. 743

Sterility Test for Sulfanilamide Powders—The report of a death from tetanus traced to a contaminated sulfonamide powder makes it evident that there is need for a test to determine their sterility. There seems to be some controversy as to the amount of heat which can be applied without altering the drug to such an extent as to render it useless and in some cases actually dangerous. The margin of safety between the amount of heat necessary to kill organisms present and the amount which will yield a product unfit for use is small. It is therefore important to have available a sterility test. The procedure which has been used by Landy and Oswald is as follows: The contents of a shaker package (5 Gm. of sulfanilamide) are transferred aseptically to a flask containing 500 cc. of sterile water. The flask is vigorously shaken for five minutes allowed to stand for thirty minutes at room temperature and shaken again for five minutes. The undissolved sulfanilamide is allowed to settle and 5 cc. of the supernatant fluid is added to each of two tubes containing 20 cc. of Brewer's medium. The tubes are incubated at 37 C. for a period of seven days and examined for evidence of growth. Brewer's medium contains a sufficient amount of sulfonamide inhibitor to permit growth of three selected test organisms: *Staphylococcus aureus*, *Escherichia coli* and *Clostridium tetani* in the presence of 50 mg. of sulfanilamide. This amount of sulfanilamide is the maximum amount which could be present per tube of Brewer's medium in the execution of the aforementioned sterility test. In order to determine the efficiency of the method in the recovery of a spore bearing pathogen from sulfanilamide powder samples were artificially contaminated with small numbers of *Clostridium tetani*. No growth was observed in the sterile sulfanilamide controls while tubes containing contaminated sulfanilamide powder showed excellent growth of *C. tetani* within forty-eight hours. This is further evidence of the extreme resistance of *C. tetani* spores to high concentrations of sulfanilamide. This procedure is applicable to other sulfonamides as well. It is necessary however, first to determine the maximum quantity of drug which is inactivated by the sulfonamide inhibitors present in Brewer's medium.

Salmonella Infections—Jager and Lamb observed in a period of one year 6 patients with *Salmonella suipastit* infection at the Boston City Hospital. Two more patients were subsequently found to be infected with *Salmonella oranienburg*, a closely related bacterium. In no case was the source of infection determined. Two of the 6 cases of *S. suipastit* infection had typhoid-like symptoms. In 1 case anatomic observations suggested that an endocardial thrombus might have been the focus of infection but this could not be established. Clinical or roentgenologic evidence of pulmonary involvement existed in 5. In 1 case a large single renal calculus caused obstruction and was associated with *S. suipastit* infection of the involved kidney. In another case there was a unilateral salpingitis with a localized fibrinous peritonitis from which *S. suipastit* was cultured. Fever was present in 5 at the time of admission and developed in another postoperatively. Two patients had chills. Diarrhea occurred once. Relative bradycardia occurred once. There was enlargement of the liver in 3 cases, in 2 however there was a history of chronic alcoholism. Jaundice occurred in 1. Chemotherapy was employed in 4 cases but did not have a beneficial effect. A moderate anemia was present in 4 cases. In several of them chemotherapy may have been a factor in its production. In 3 cases the initial white cell count was low or normal whereas in 3 it was elevated. In 4 of the 5 cases in which blood cultures were made the organism was recovered. Urine cultures were positive in only 1 case. Stool cultures were negative in every case as were also sputum and throat cultures. Cultures of the wounds in the 2 cases with surgical complications gave repeatedly positive results. In 4 instances the patients' serum agglutinated their organisms. *S. suipastit* can be separated from other members of the *Salmonella* group by its selective fermentation reactions and by agglutinations.

with specific antisera. It belongs to the typhoid-paratyphoid organisms. The six strains of *S. supestifer* isolated belong to the type *Salmonella cholerae-suis*, var. *kunzendorf*, a monophasic organism. *Salmonella oranienburg* is a rare pathogen. The selective fermentation reactions of this organism are identical with those of *Salmonella paratyphi C*. If, however, fermentation tests with Stern's glycerin medium and Bitter's rhamnose medium are carried out it is possible to make a differentiation, since *S. oranienburg* gives positive fermentation reactions on these two mediums, whereas *S. paratyphi C* yields negative reactions. With stock *S. supestifer* serum *S. oranienburg* gives a somitic (finely granular) type of agglutination. This is in accord with their common somitic antigens. The diphasic *S. supestifer* (*S. cholerae-suis* var. *kunzendorf*) failed to agglutinate the two *S. oranienburg* strains. This is to be expected since the two organisms have distinct flagellar antigens.

Rheumatoid Arthritis as Cause of Increased Protein in Cerebrospinal Fluid—Ludwig and his associates point out that the neurologic manifestations of rheumatoid arthritis are numerous, variable and at times so striking as to simulate disease of the central or peripheral nervous system. The present investigation concerns the aspects of the cerebrospinal fluid in rheumatoid arthritis. The cerebrospinal fluids from 101 patients with rheumatoid arthritis, 42 having spondylitis with or without peripheral arthritis, and 59 having involvement of the peripheral joints alone, were examined. The only significant abnormalities observed were increased protein contents, abnormal colloidal gold curves or a combination of the two. Nine, or 12 per cent, of the 59 patients with rheumatoid arthritis involving the peripheral joint alone and 16, or 38 per cent, of the 42 patients with spondylitis exhibited such abnormalities. Fifteen of the 16 patients with increased cerebrospinal fluid protein had either spondylitis or symptoms suggesting spinal involvement. This fact points strongly to a relation between an elevation of the spinal fluid protein and the presence of rheumatoid arthritis in the spinal and sacroiliac articulations. Cerebrospinal fluid alterations occurred more frequently in the spondylitis patients with severe pain or sciatica or both and hence presumably with a higher degree of inflammatory activity. Factors probably involved in the production of these abnormalities are alterations in the serum proteins and increased permeability of the meninges from their proximity to inflamed articular tissue. Attention is called to the diagnostic difficulties presented by patients with rheumatoid spondylitis and increased cerebrospinal fluid protein, with particular reference to their differentiation from cases with ruptured intervertebral disks.

Clinical Use of Mixtures of Insulins—Sparks and John adequately controlled 140, or 93.5 per cent, of 150 ambulant diabetic patients by a single daily injection of insulin. Of the series 53 per cent received protamine zinc insulin and were controlled by it alone, 38 per cent a mixture of protamine zinc insulin and amorphous insulin and 2.5 per cent crystalline zinc insulin. The remaining 6.5 per cent (10 patients) form a heterogeneous group. The patients who were adequately controlled by protamine zinc insulin either had mild to moderate

diabetes and required 30 units or less per day or were those in whom diabetes developed after 40 years of age. For the 47 per cent who cannot be adequately controlled with protamine zinc insulin, who are determined by the taking of their blood sugar after each meal, protamine zinc insulin and amorphous insulin given at one injection has proved satisfactory in 38 per cent of the total. In place of such stock mixtures of fixed proportions of the two insulins the authors at the time of injection first take the amorphous insulin into the syringe, add the proper amount of protamine zinc insulin and make the injection immediately. This order is followed so that no protamine zinc insulin may be introduced into the bottle of amorphous insulin. This manner of mixing the insulins can be varied to meet the needs of each individual as may be necessary from time to time, as proportions necessary for adequate control have varied widely. Most of the patients treated with the mixture had moderately severe diabetes, so that the total dose of insulins was between 40 and 60 units. It was used with advantage for 1 patient receiving a total dose of only 15 units, and at the other extreme were 2 patients given 70 to 80 units and 90 units in all to another 1. The juvenile diabetic patients were the ones who benefited most from the mixtures even when the total dose was small. There were no patients who could not accomplish the mixing of the two insulins.

Cooking of Garbage—To determine the minimal time required for cooking garbage to destroy trichinae in pork scraps which it contained, Wright and Bozicevich introduced pieces of trichinous pork into garbage cooked by steam in open tanks. The pieces of pork varied in dimension from 1 by 1 by 1 inch to 6 by 6 by 4½ inches and in weight between 20 Gm (0.04 pound) and 2,297 Gm (5.06 pounds). The samples were placed in the garbage while it was still cold before the steam was turned into the tank and held in the tank for various periods after the garbage came to a boil. The internal temperature of each piece of pork was ascertained by means of a meat thermometer inserted into the center of the sample. The data from the experiments warrant the conclusion that the boiling of garbage for thirty minutes in an open container will effect the destruction of trichina larvae in pieces of pork up to 3 inches in thickness and probably in pieces of pork of greater thickness provided the garbage is allowed to cool gradually. Such a procedure would seem to constitute an effective measure for preventing the transmission of trichina infection to swine man tamed on garbage and thus aid in the control of swine trichinosis primarily and human trichinosis secondarily.

Use of Intrapelvic Coagulum in Pyelolithotomy—Dees outlines a new approach to the problem of the surgical removal of renal calculi. The incidence of recurrence after pyelolithotomy is too high and this, he believes, is due to the incomplete removal of stones at operation. The new technique promises complete removal of all free renal calculi regardless of their size or position within the renal pelvis. A coagulable substance (clotting globulin) is injected into the renal pelvis at open operation. The resulting clot completely fills the pelvis and forms a perfect mold of its ramifications. Within this coagulum are incorporated all free renal calculi. The coagulum together with all stones enmeshed within it may then be removed through a pyelotomy incision. The technic has been used in 5 cases of nephrolithiasis without apparent ill effect. Although the method is still in an experimental stage calculi that probably would not have been removed by pyelolithotomy as usually performed have been removed by this means.

Acute Hemolytic Anemia in Fertilizer Workers—Within the last three years Wilson and Mangun encountered 3 cases of acute hemolytic anemia with hemoglobinuria which occurred under similar circumstances in the fertilizer industry. Subsequent investigation clearly points to a metallic poisoning an industrial hazard previously unsuspected in the fertilizer industry. An active hemolysis was isolated from the blood of 1 of the patients and from the urine of another. The authors believe that adequate ventilation of ships carrying fish scrap to fertilizer mills would prevent the occurrence of this industrial accident.

Unsuccessful Sulfonamide Therapy of Pneumonia—Flippin states that the following should be thought of as possible causes when sulfonamide therapy is not successful: (1) pneumonia not due to sulfonamide affected organisms, (2) improper selection of a drug (3) belated chemotherapy (4) inadequate chemotherapy, (5) drug toxicity, (6) presence of antisulfonamide substances and (7) failure to employ other established therapeutic measures.

Multiple Gastric Polyposis—Since 1926 when they collected 84 cases Pearl and Brunn have collected 41 cases of multiple polyps of the stomach from the literature and to this they add 3 proved cases of their own. Multiple gastric polyposis may be congenital (neoplastic) or inflammatory (hyperplastic). The two types may often be differentiated on gross examination alone. Microscopically in neoplastic polyps the muscularis mucosae enters the tumor for a variable distance and usually becomes fragmented or split with the submucosa entering the tumor for a variable extent. In the hyperplastic type the muscularis mucosae is intact and forms a delineating membrane the submucosa plays no part in the formation of the tumor. Borderline cases may be difficult to classify. The symptoms are not characteristic, epigastric pain and tenderness were most frequent. Bleeding in the vomitus stool or gastric content was found in more than 50 per cent of the patients. In pedunculated tumors and those near the pylorus, separation of polyps or pyloric obstruction is more likely. Some patients have had symptoms for more than twenty years. Physical changes may be indefinite or entirely lacking. Diagnosis may be difficult. The roentgenogram may fail to differentiate multiple polyps from chronic hypertrophic gastritis retained food bezoar or sarcoma. The correct diagnosis is made most often at operation. Roentgenology and gastroscopy are complementary their combined use will greatly enhance diagnostic acumen. Free hydrochloric acid was absent from the fasting gastric content of almost every patient. Careful search should be made in the gastric content for particles of tumor which may establish the diagnosis. In the previous series a malignant alteration was observed in 12 per cent and in the present series in 19 per cent. This alone argues for radical surgical removal of the area bearing the tumor. The results are greatly superior in gastrectomized subjects.

Mesonephroma or Teratoid Adenocystoma of Ovary—Stromme and Traut report 10 cases which fulfil the criteria outlined by Schiller for mesonephroma or teratoid adenocystoma of the ovary. In their series they have usually been at a loss to demonstrate structures which resembled the architectural arrangement of wolffian glomeruli. The tumors abounded in acini into which papillary tufts of epithelium projected with or without a supporting connective tissue stalk but any one of several well recognized ovarian or uterine tumors could be named mesonephric if the demonstration of this arrangement of cells should be taken as the criteria of such origin. They are skeptical of Schiller's explanation of the etiology of this group of tumors and prefer not to accept his term of mesonephroma ovarii. They are convinced that the tumors are not

rule, that they form a morphologically distinct group of ovarian tumors with a characteristic life history and that for this reason they should have a distinctive name (teratoid adenocystoma). These tumors are not merely a hydropic form of serous cystadenoma, for they almost invariably produce a mucin-like substance which reacts to the usual stains for mucin. While the mucin stain is nonspecific, the fact that it is positive differentiates it from the serous group in which it is not positive. This suggests a probable relationship to wolffian or teratoid antecedents. These neoplasms are different morphologically and in their mode of growth from the pseudomucinous cystadenomas. Whether benign or malignant, they are essentially solid tumors which tend to become cystic only as they degenerate.

Experimental Study of Underwater Concussion—

Greaves and his associates present data on the effects of underwater concussion on rats, guinea pigs and goats. The amount of explosive necessary was 5 Gm of tetryl for adult white rats and 6 Gm for adult guinea pigs. Death immediately following the blast was due to pulmonary damage. The respiratory function of the lungs was immediately and totally destroyed. The animals were not rendered unconscious by the blast but continued their swimming motions for several seconds. Cyanosis appeared and the nose and mouth exuded a bloody, frothy liquid. Occasionally bloody froth was present about the nares, and the respirations were shallow and rapid. Some of these animals died after a few hours. Those that survived regained

their normal actions within a short time and demonstrated no further ill effects. The lesions produced under comparable conditions in all animals were surprisingly uniform. Pulmonary lesions were always found if any injuries resulted from the blast, but intestinal lesions were not constant. None of the other organs or tissues in the thorax or abdomen showed injury. No cerebral or central nervous system lesions were encountered. A few fractured extremities resulted from explosions of high order. The determining factor in the production of injuries by blast is the presence of air or gas in the tissues; the more air or gas that is present, the greater is the injury. When a compression wave greater than 500 pounds per square inch strikes the body it is transmitted through the tissues and, on striking the air within the lungs or the gas bubble within the gastrointestinal tract, it breaks through into the gaseous medium with a shredding effect, tending to "blow off" the surface of the tissues exactly as it blows off the surface of water when it breaks through into air. Gastrointestinal tissue, as such, is resistant to the effects of the compression wave, but if gas is present in the lumen the wave will shred as it breaks through. If the gas is displaced without compression, the only lesion will be a hemorrhagic area of the wall, marking the site of the shredding. Perforation will occur when the gas bubble is trapped. If the wall has been sufficiently weakened by the shredding injury it will break down before the reexpanding bubble and a "blow out" perforation will result. Injuries were minimized when the animals were protected about the trunk by a lifejacket covering of foam rubber or kapok that was not waterlogged. Animals completely protected by dry kapok received only minimal lesions when subjected to two and a half times the lethal charge. The protective action of kapok and foam rubber is due to their ability to disperse the compression wave sufficiently to prevent or to minimize its destructive effect. Any protective device worn by men should be of the sleeveless coat type. The kapok should be enclosed in muslin bags, which in turn are encased in a pliable, waterproof material. It should have a padded collar attached that fits snugly about the neck when tied in front. The coat should be slightly double breasted and the skirt should reach to the greater trochanters of the femur. The jacket should have a padded "tail" to be drawn and tied between the legs to protect the scrotum and testicles. The thickness of the pads should be the same as those used in the standard Navy life jacket.

Experimental Immersion Blast Injury—Friedell and Ecklund determined in animals the types of abdominal and other injuries that immersion blast causes. Two types of abdominal lesions observed were a hemorrhagic condition of the muscularis portion of the intestinal wall and perforations and larger tears in the intestinal wall. The lesions in the chest were symmetrical hemorrhagic areas on the surfaces of the lung nearest to the explosive source, thus the dependent edges of the middle lobes were usually involved and the posterior surface when the back was turned toward the blast. The severity of thoracic lesion depended on the distance of the explosion, the size of the charge and the protection afforded the thorax. Thoracic involvement usually accounted for the fatal outcome. Abdominal lesions were not produced except when the pulmonary damage was so severe that death ensued in five to ten minutes after the explosion. All such animals were fairly lively for two to three minutes, air hunger then ensued, the eyes began to bulge, and minor convulsions followed. With a chamber devised to minimize the effects on the thorax the lungs were protected so that previously fatal explosive conditions were no longer lethal. However, abdominal lesions were present and as the force of the charge grew greater the hemorrhagic lesions gave way to perforations. When the force of the charge was apparent, perforations were frequent. The effect of charges was apparently somewhat minimized when the animal was placed on its back. In the patients observed by the authors after the battle of Midway, they felt that possibly life jackets prevented severe injury to the lungs as to cause death and that the unprotected abdomen bore the brunt of the explosion. This can

be borne out by experiments in which the previous lethal condition was repeated, except that the chest was protected. Perforations then occurred in the intestinal tract. At necropsy the changes in the chest were not severe enough to explain the lethal outcome. Peritonitis appeared in 1 animal which survived the pulmonary blast injury for twenty-three hours thus duplicating the picture encountered in some instances of human immersion blast injury. The authors suggest that the life jackets be made to cover the abdomen.

Night Blindness Improvement with Vitamin D—Of all ocular conditions giving rise to night blindness Knapp states that retinitis pigmentosa stands in the forefront. Fortunately it is a rare disease. Night blindness may be caused by a deficiency of at least two vitamins A and D. Another condition often complicated by night blindness is myopia. Among 93 patients with various degrees of myopia 64 complained of poor vision in reduced illumination. As routine treatment these 64 were given 60 drops of viosterol and at least 1 Gm of available calcium. With some the vitamin D dose was increased to 200 drops daily. After six to twenty-seven months of observation during which time the patients were checked at least once a month there was an actual reduction of the myopia in 20. Casts of the anterior segment of many eyes and in 1 instance a fundus photograph before and after treatment proved beyond doubt that the eyeball in both its anterior and posterior segments may shrink following treatment with vitamin D and calcium. Of the 64 persons suffering from poor vision at night 46 noticed distinct improvement in respect to their nyctalopia in no way dependent on their myopic status. Several weeks usually elapsed before definite clinical improvement was seen. The majority of those patients whose myopia was reduced spoke of their greater ability to see after nightfall and others had better vision at night when their myopia was stationary or even in the presence of an increase of their near-sightedness. In 16 the condition apparently remained the same. During the treatment of both the patients with retinitis pigmentosa and the myopia toxicity was watched for. Seldom did a toxic sign develop—a mild rash, nausea, vomiting or constipation—but these symptoms disappeared soon after the medication was stopped or reduced.

Primary Atypical Pneumonia—Dingle and his associates members of the Commission for the Investigation of Atypical Pneumonia and Other Respiratory Diseases at Camp Claiborne Louisiana report that clinically epidemiologically and etiologically atypical pneumonia at Camp Claiborne was in general agreement with the observations of other investigators. The infection occurred in epidemic and in endemic form. The causation has not been ascertained. The most characteristic clinical feature of the syndrome was the late development of physical signs in the lungs in contrast to the comparatively extensive x-ray evidence of the lesions. This observation emphasizes the need for early and repeated x-ray examination and for frequent physical examination during the course of the acute illness to determine the true incidence of the disease. The clinical and epidemiologic data support the possible relation between atypical pneumonia and certain of the minor acute illnesses of the respira-

tory tract without demonstrable pulmonary lesions observed by Gallagher and by Reimann and his associates. The agent or agents undetermined as yet, causing atypical pneumonia may produce a constitutional reaction of varying degrees of severity both with and without obvious pulmonary involvement. At present there is no specific measure for determining the proportion of the minor illnesses which are of the same causation. The factors determining the incidence and the conditions incident to the epidemic remain obscure. The existence of a non-human reservoir of infection was not discovered, but neither was its possibility completely excluded. Its widespread occurrence at the camp and its scarcity among the population suggested that susceptibility to the pneumonic form was low. Its epidemiology is consistent with the hypothesis that the disease is communicable from person to person and that inapparent instances act as the effective spreading source of the infection. No evidence was obtained that predisposing factors, such as chilling, fatigue or previous infections of the upper respiratory tract, were important in the pathogenesis of the disease. If an appreciable number of minor illnesses are of the same origin as some evidence now indicates the infection must be considered an important disease of the respiratory tract which causes disability not only in the armed forces but in the civilian population.

Primary Atypical Pneumonia and Malaria—Campbell reports 50 cases of primary atypical pneumonia in Panama and the Canal Zone complicated by concurrent malaria. In a locality in which malaria is endemic, cases of primary atypical pneumonia must be considered with the possibility of a dual infection in mind. Such cases can be separated into two groups: those admitted to the hospital with the pneumonia in many of which subsequently a blood smear is positive for malarial parasites and those admitted for malaria in which atypical pneumonia develops later on. In the first group the onset is usually gradual and the patient complains of having felt bad for several days. There are a nonproductive cough, vague pains in the chest, sore throat and fever. Although uncomfortable he is not prostrated. His fever is usually intermittent, and the temperature varies between 100 and 102 F. occasionally it may be higher. Defervescence by lysis usually begins about the fifth to the eighth day of illness. Moist rales can sometimes be heard at the onset and can usually be heard at the height of the pulmonary involvement. Approximately 68 per cent of the patients of this group had blood smears positive for malarial parasites. This 'secondary infection' seems to have little or no effect on the eventual recovery except that hospitalization to eradicate the parasite is longer than is usually necessary for the pulmonary infection alone. The two diseases run independent concurrent courses. Treatment of the pneumonitis is symptomatic. Codeine is often necessary to control the cough. When malaria is present it is treated with quinine or atabrine in the routine manner. There have been no deaths. The malaria of the patients of the second group responds well and is controlled rapidly but during convalescence a nonproductive cough may develop with pain and discomfort in the chest and an elevation of temperature. This usually may occur over several days but may be ushered in suddenly with a chill. Examination may or may not reveal positive physical signs in the chest. The diagnosis is made by x-ray examination. The complication develops in only a small percentage of the total cases of malaria but it is by no means uncommon and must be borne in mind. Treatment is symptomatic and antimalarial measures are continued as usual.

Early Diagnosis of Gas Gangrene—McClean and his collaborators studied the possibility of detecting the presence of actively proliferating pathogenic organisms at a stage when the infection cannot be recognized by clinical or ordinary bacteriologic examination. Organisms of the gas gangrene group, staphylococci, streptococci and pneumococci produce, in addition to their recognized toxins, substances which cause an immediate increase in the permeability of the connective tissues. These diffusing or spreading factors are closely associated, it not identical with a group of enzymes that hydrolyze the mucopolysaccharide known as hyaluronic acid, which is widely distributed in the connective tissue. The enzymes are therefore called hyaluronidases. The presence of hyaluronic acid causes the infecting organisms to produce an increased amount of the enzyme and a vicious circle is set up which promotes the extension of the infection. It was of interest to determine how early in an infection these bacterial enzymes could be detected in the edema fluid or wound exudate, the distribution of these substances in the body fluids and their correlation with the progress of infection. If these enzymes could be detected at an early stage, the knowledge might provide a rapid means of early diagnosis, a more vigorous and objective antitoxin therapy and less extensive operative excision with a consequent reduction in both mortality and mutilation. Although experimental evidence indicates that hyaluronidase and lecithinase can be detected in the edema fluid as soon as there is sufficient to collect for examination, the authors do not know how early these enzymes will appear in the infected wound or how the time of their appearance will be correlated with clinical signs of infection. Animal experiments suggest that this is likely to be early in the infective process and before local changes are diagnostic. It remains to be proved whether the fact that the infecting organisms are proliferating in sufficient numbers to produce these enzymes in the tissues is evidence of active wound infection or whether this proliferation can occur when the organisms are present only as apparently harmless contaminants. The authors believe that the methods can be applied to the examination of clinical material. They suggest that a negative result from the examination of a wound exudate should not induce a false sense of security and should not be allowed to contraindicate the routine administration of antitoxin or sulfonamide compounds or both.

Prefrontal Leukotomy—Fleming and McKissock report the results of prefrontal leukotomy performed on 15 additional patients. Of this number 12 were melancholic, 1 of the remaining 3 obsessional, 1 schizophrenic and 1 manic-depressive. Of the 12 patients with melancholia, 7 have made a complete recovery and 1 has shown considerable improvement but the other 4 so far have shown little improvement. The obsessional patient has completely recovered, but the schizophrenic remains much the same although quieter, while the manic-depressive is improved. Two patients with involutional melancholia were not doing well but suddenly began to improve after being spoken sharply to and told that they must "pull themselves together to go home." One patient, with schizophrenia, has had a single seizure since the operation, and 1 had a series of thirteen seizures, but as her blood pressure was 240 mm of mercury it is possible that the seizures were of hypertensive origin. Several of the patients have found complete "peace of mind" after the operation, and these were patients who for years had been suffering torment. The operative risk seems small. There have been no deaths in 15 cases. Of the involutional melancholic,

2 had had fifteen electric shocks followed by a prolonged shock of twenty seconds with no clinical improvement. One of these has shown no improvement after leukotomy, the other a moderate degree of benefit. Some of the patients had urinary incontinence after the operation. The impression was gained that the more severely mentally affected the patient is before the prefrontal leukotomy, the more likely he is to have urinary incontinence after it.

Results of Prefrontal Leukotomy—Hutton reports the results obtained on 50 patients subjected to prefrontal leukotomy. Of the two deaths (4 per cent mortality) only one could be attributed directly to the operation. It was due to cerebral hemorrhage caused by accidental section of the anterior cerebral artery. In most of the cases the postoperative course has been uneventful, enuresis, usually transitory, has occurred in several cases, but other neurologic complications have been rare. In view of the radical nature of the treatment, it has been advocated only in cases in which the prognosis was poor and in which other methods had been tried and had failed. Considering the chronicity of many of the cases the results are extremely encouraging. Not a single patient is recorded as being worse after the treatment than before, and even the patient with the least satisfactory results is usually found to be quieter, less impulsive and more amenable. The treatment has been tried in varying forms of mental disorder and improvement has been obtained in every type. Results seem to be best when there is a very strong negatively toned emotional factor, such as apprehension, anxiety, inadequacy or guilt. The least successful results have been obtained in cases of dementia simplex characterized by emotional apathy and general mental reduction. The rehabilitation after the operation is of the utmost importance; personal attention and encouragement are essential, and where these are lacking the results tend to be disappointing. The greatest success is obtained with patients of good intelligence whose relatives have sufficient interest, affection and understanding to help in this process of reeducation. Prefrontal leukotomy converted many patients suffering from supposedly hopeless mental disorders into contented and useful members of society.

*Dysentery in Middle East with Special Reference to Sulfaguanidine Treatment. N. H. Fairley and J. S. K. Boyd—p. 253
Child Mortality in Lagos, Nigeria. E. C. Smith—p. 287
Bactericidal Effect of Tin and Its Application to Treatment of Typhoid Fever. R. Reiller and K. Marberg—p. 305

Dysentery in Middle East with Reference to Sulfaguanidine—Fairley and Boyd state that in the Middle East dysentery is mainly fly borne. Bacilli causing dysentery included the six Flexner and three Boyd strains, as well as *Bacterium dysenteriae* of Shiga, Schnitz and Sonne type. Sigmoidoscopy is valuable in the diagnosis of subacute and chronic dysentery, in the control of treatment and in detection of the carrier. Material collected by direct swabbing of the ulcers may yield positive findings when previous culture studies of the stools were negative. Therapeutic results proved disappointing with polyvalent antidyenteric serum. The refined antidyenteric Shiga serum prepared by partial peptonization produced clinical improvement. The benefit was too often only temporary. The serum was given intravenously in a dose of 5 to 10 cc (100,000 to 200,000 international units), serum sickness or other untoward reactions were not observed. The cases treated with sulfaguanidine comprised over 500 cases. The analysis has been confined to 96 Shiga cases. The conclusion reached was that sulfaguanidine constitutes a specific cure for this disease. It exerts a bacteriostatic or bactericidal action which rapidly leads to a decrease in toxemia and to cessation of damage to the intestine. In subacute and chronic cases which had been resistant to other treatment were observed to heal rapidly. The drug is relatively non-toxic and never led to hematuria or renal blockage. The action of sulfaguanidine, which is bacteriostatic, and antidyenteric Shiga serum, which is antitoxic, are mutually complementary. The most important indication for the administration of antitoxin is in fulminating or severely toxic cases of dysentery.

Sjögren's and Plummer-Vinson's Syndromes and Riboflavin Avitaminosis—Sjögren called attention to the fact that the filament keratitis described by Leber in 1882 is not merely an ocular manifestation but part of a general syndrome characterized by extreme dryness of the mucous membranes. Franceschetti, as well as Steimann, found normal vitamin A values in patients with Sjögren's syndrome. Franceschetti points out that Sjögren's syndrome resembles the Plummer-Vinson syndrome. Meulengracht and Bichel detected a close resemblance between the Plummer-Vinson syndrome and ariboflavinosis. In the Plummer-Vinson syndrome is due to riboflavin avitaminosis then the same can be said of the syndrome of Sjögren especially since the latter presents the ocular sign suggestive of ariboflavinosis and the former does not. Franceschetti found a porphyrinuria in 2 patients with Sjögren's syndrome. He feels, however, that it is not always safe to base the cause of a disorder on analogies. The increased sedimentation rate and the frequency of joint symptoms does not permit the exclusion of an infectious factor. The author injected daily into 2 patients with Sjögren's syndrome for a week 2 cc of a preparation containing thiamine, riboflavin, nicotinic acid, adermine (B₆) and pantothenic acid. One of the patients was favorably influenced so far as the condition of the buccal mucous membrane was concerned, in the other only the rhagades were influenced. He concludes that although the role of riboflavin in the syndromes of Plummer-Vinson and of Sjögren is far from clarified one is justified in pursuing investigation along these lines.

Epidemic of Virus Pneumonia—Haemig and Heyden report an influenza-like epidemic which broke out in an infantry battalion at the end of February 1942. Of 105 men who contracted the disorder 59 had roentgenologically demonstrable pulmonary infiltrates. The onset was acute with headache, dry cough, high intermittent temperature and profuse sweats but without dyspnea. There was a discrepancy between the slight or entirely absent auscultatory signs and the roentgenologic findings. The infiltrates were delicate, small and round or fan shaped. They originated in a widened hilus. Their absorption was accomplished within one to three weeks after the lytic defervescence. Chemotherapeutic preparations had no effect on the fever. The scanty and uncharacteristic sputum contained a mixed flora. The leukocytes at the beginning were either normal or diminished in number and there was considerable deviation to the left. The leukocytes frequently rose to 15,000 in the course of the disorder. The sedimentation reaction was not uniform; usually it was slightly increased. The course was benign. Complications developed in only 4 cases. Dense pneumonic infiltrates with effusion were present in 3 of these. The pathogenic organism could not be determined. The authors

assume that it was virus pneumonia because the symptoms and the character of the pulmonary infiltrates resembled those of the atypical pneumonia described by Smiley and others.

Meynet's Nodes—Junet and Alphonse point out that Meynet in 1875 called attention to the appearance of subcutaneous nodules in the course of acute articular rheumatism. Other observers subsequently referred to these nodules as Meynet's nodes. Neglected for many years, they have received more attention in the last two decades, chiefly because they are encountered in all forms of rheumatism and are regarded as a link between acute articular rheumatism and chronic infectious rheumatism. Some observers, particularly Coombs, regard them as the most specific manifestation of the disease. Meynet's nodes are rarely encountered in Geneva in spite of the relative frequency of acute articular rheumatism and of chronic rheumatism. The authors report the case of a girl in whom the nodes constituted the only typical manifestation during the early stage of cardiac rheumatism. Acute articular rheumatism, chronic infectious rheumatism and Still's disease belong to one nosologic family. Meynet's nodes are their common manifestation.

- Focus of Contagion in Tuberculosis of Children M. Santos de Cossio —p 141

Painful Hepatic and Perihepatic Syndromes in Cardiac Insufficiency—Ferrer y Solericens points out that in cardiac insufficiency the true cardiac pains are often accompanied by pain in other organs involved in the existing circulatory failure. In chronic congested liver pain is dull and continuous. If the congestion increases suddenly as the result of temporary insufficiency of the right ventricle paroxysms of pain may appear in the right hypochondrium; they resemble severe hepatic colics. This is the case particularly when the right ventricle empties its blood into rigid sclerotic lungs incapable of storing blood. Cardiac insufficiency may develop in the course of diseases of the liver, the bile passages, the stomach and the duodenum and may aggravate and prolong them. Acute or subacute dilatation of the stomach and duodenum may be observed in insufficiency of the right heart with hepatic cirrhosis and pulmonary sclerosis. Diseases of the liver and of the neighboring organs may cause cardiac insufficiency in patients whose cardiac reserve is small or they may intensify an already existing cardiac insufficiency.

Intracranial Hemorrhage in the Newborn—According to De la Villa intracranial hemorrhages are a frequent cause of death in newborn infants. He observed 74 fatalities among 3,000. Intracranial hemorrhage was the cause in 42 or 56 per cent. Congenitally weak children develop intracranial hemorrhages most frequently. Vitamin K is valuable in the prophylaxis and treatment of intracranial hemorrhages of the newborn. The vitamin should be given to all parturient women. The newborn should be bled within the first eight hours after delivery.

- *Meniere's Vertigo A. Asenjo and S. Riesco —p 452
- Experimental Pathogenesis of Epilepsy and Hysteria F. Sal y Roas —p 450

Meniere's Vertigo—Asenjo and Riesco treated 18 patients with Meniere syndrome by administering 6 to 8 Gm of potassium chloride daily, 0.25 Gm of vitamin B₁, nicotinic acid, phosphorus and a diet rich in vitamin B. The treatment was continued for four to six months. The immediate and late results were good in 12 patients who were observed for more than three years. The immediate results were good in 2 patients who recently completed the treatment. Vertigo was almost entirely controlled. Deafness and buzzing ear sounds persisted. Resection of four fifths of the acoustic nerve was resorted to in 3 of the 4 cases in which the medical therapy failed. The results were excellent in all 3.

Book Notices

Medico Legal Blood Group Determination Theory Technique, Practice By David Harkley M.D. B.Sc. F.R.C., The Laboratories of the Inoculation Department St. Mary's Hospital, London. Cloth. Price \$1.50. 124 pp. 119 with 11 illustrations. New York: Grune & Stratton, London: William Heinemann Ltd. 1941.

This small volume fulfils the promise of the title. It is divided into three sections. The first gives a brief but clear picture of the present day knowledge of the A, B, O and M, N systems of blood groups and types, including the inheritance, distribution in tissues other than blood and the principles of medicolegal application. Section two describes in considerable detail the technique of the author for paternity tests and for blood and secretion stains. It is based on the capillary tube technique of Wright. In the last section (the largest of the three) the results in sixty-five paternity tests with ten exclusions and records of studies of blood, semen and saliva stains in fifteen criminal investigations are presented. Proposed bastardy bills and an interesting report of a committee of the House of Lords on the bastardy bill should be read by those who are interested in passage of laws permitting the use of blood groups in paternity litigation in our courts. The book can be recommended to all who are interested in the subject.

Family Treasures A Study of the Inheritance of Normal Characteristics in Man By David D. Whitney Ph.D., Professor of Zoology, University of Nebraska, Lincoln. Cloth. Price \$1.50. Pp. 299 with 211 illustrations. Lancaster, Pa.: J. B. Lippincott Press. 1942.

If one possesses a family photograph album covering three or four generations of ancestors and close relatives, one has therein a convincing demonstration of the inheritance of many normal human traits. Professor Whitney has made liberal use of his own family photographs as illustrations for his book. The best part of the book consists largely of photographic illustrations of the recurrence of similar characters in two or more generations of a family. These characters include shape of the ears, nose, lips, chin, jaws and teeth, form, color and pattern of head hair, face and body hair, shape, color and peculiarities of the eyes, shape, size and peculiarities of the hands and feet, fingers and toes and finger and toe nails, peculiarities of the skin such as dimples and freckles, general health and vigor, temperamental traits and special abilities, and numerous other miscellaneous human traits revealed by photographs. For the physician there is little of interest in the book, for the author has purposely omitted all traits that are obviously pathologic though he does allow himself to mention such abnormal traits as brachydactyly, polydactyly, color blindness, hemophilia, baldness and susceptibility to allergic symptoms. Little attention is given to the many human traits that differ quantitatively and which have been dealt with by exact biometric methods. No mention is made of the extensive use of twins in assessing the relative shares of genetic and environmental factors in determining many human differences. Nearly all characters are dealt with as though inherited as simple mendelian dominants or recessives, whereas it now seems clear that most human traits have a more complex mode of heredity. For the general reader, however, it may be wise to simplify the story of heredity even to the extent of oversimplification in order to make the point that nearly all human differences have a hereditary basis and are not altogether, as so many believe, the result of differences in the environment or maternal impressions. The main purpose of the book is to humanize the science of human heredity. This purpose it successfully accomplishes. The book should have a wide sale, even in wartime.

Insuficiencia circulatoria poriférica Colapso—shock Por Blas Mola, Doctor en medicina docente libre de patología médica de la Facultad de medicina de Buenos Aires. Papei. Pp. 80 with 5 illustrations. Buenos Aires: Librería y editorial "El Ateneo" 1942.

This short monograph is an enlarged version of a series of lectures given by the author before several audiences in the Argentine Republic. Although the book is essentially practical the reader is prepared by an excellent chapter on physiopathology of the circulatory system logically leading to those concerned with pathogenesis and etiologic factors. The remaining chapters are devoted to the clinical symptoms, differential diag-

nosis, prognosis and treatment. The indication of the different therapeutic means to be used in each case is especially good. The sources of the monograph are largely American, e.g. Cannon, Moon, O'Shaughnessy, but important Argentine contributions are also quoted. The subject is developed with remarkable clarity and conciseness, and the monograph appearing in these days is most timely. It should be read by the general practitioner and carried in the pocket by the military physician.

A Surgeon's Fight to Rebuild Men An Autobiography By Fred H. Albee M.D. F.A.C.S. F.R.C.S. Foreword by Lowell Thomas. Cloth. Price \$1.50. Pp. 334 with 11 illustrations. New York: E. P. Dutton & Co. Inc. 1943.

The autobiography of Fred Albee could almost be accepted as a history of modern bone surgery. Every page of this thoroughly interesting volume is stamped with his dynamic personality. Many who read the book may question some of the claims made by Dr. Albee of having originated so many of the now widely accepted principles of bone surgery. No reviewer, however, can be honest with himself or with the medical profession in general without acknowledging the tremendous debt which the orthopedic surgeon of today owes to Fred Albee who, together with other pioneer surgeons, helped to change the practice of bone and joint surgery from that of manipulation and strap and buckle therapy to one of the most highly skilled of all surgical specialties. This book constitutes much more than a partial history of orthopedic surgery. It is adventure drama and philosophy. Albee has been spoken of as a bone carpenter. He is infinitely more than that. Throughout the pages of this book he is an architect and a creator of methods and ideas. As this book unfolds the interesting events of his life, the reader will become acquainted with the constructive imagination and driving energy of Albee the man as well as Albee the surgeon.

The Infectious Diseases of Domestic Animals with Special Reference to Etiology, Diagnosis and Biologic Therapy By William Arthur Haslam D.V.M. D.Sc. Professor of Bacteriology and Dean of the Faculty of Veterinary Medicine, New York State Veterinary College, Cornell University, Ithaca, New York. Cloth. Price \$6. Pp. 665 with 146 illustrations. Ithaca, New York: Comstock Publishing Company, Inc. 1943.

This is a first edition. The broad field indicated by the title is considered in the manner in which courses in veterinary pathogenic bacteriology are usually taught, but the breadth of the information has not heretofore been available in any one textbook. As the author states, "the work is less than a text book of bacteriology in that a knowledge of the general principles of the subject is taken for granted and thus part of the usual text is omitted." An introductory division of the text contains a consideration of the general fundamentals of disease causation and transmission and of immunology. The succeeding major divisions are devoted to pathogenic bacteriology, mycology and protozoology and to virology. The methods of preparation of materials and the techniques usually employed for the study of the taxonomy, cultural features and physiology are largely omitted. The pertinent information, however, concerning the results that may be expected from such studies of the various micro-organisms is briefly stated. Similarly given are the characteristics of nonpathogenic micro-organisms that are close relatives of the pathogens. The major part of the text space is devoted to the pathogenic attributes and the methods of transmission of the infectious agents and to important diagnostic features of the infectious processes and methods of their control, including hygiene, biologic treatments and chemotherapy.

The subject material is confined to 565 text pages. The six major divisions are divided into forty-four chapters. The chapter labels are derived from the generic names of the various micro-organisms or from certain features of their morphology and physiology or from the tissue tropisms of the infectious agents. References to important literature are cited throughout the text and grouped for convenience at the end of various divisions. Excellent illustrations are given which include cellular and colonial characteristics of various micro-organisms, gross and microscopic pathology of various disease processes.

The subject of the transmission of infectious agents in animals to human beings is thoroughly presented. This information imparts to the text a high public health value.

presentation of the pertinent knowledge concerning the infectious diseases of the domesticated animals by an author whose substantial contributions to and teaching in this field of science are well known bids well to insure the text having a wide usage among veterinary students, practitioners and investigators in the broad field of infectious diseases.

This authoritative volume is worthy of the highest praise and can be recommended without reservation to physicians and others desirous of having in a single volume the pertinent facts concerning the infectious diseases of domestic animals. The book is a notable contribution to the literature of comparative bacteriology and pathology. The publishers have contributed admirably to the enterprise. The text is attractively and substantially bound and represents a fine example of good book making.

Electrocardiografía practica Por Luis Herve L. Prólogo del Prof. A. Garrido Silva. Second edition. Paper. Pp 110 with 36 illustrations. Santiago de Chile. Central de publicaciones 1942.

This monograph on practical electrocardiography, written in Spanish, by one of Professor Silva's associates, compares favorably with the more elementary of the American publications on this subject. The author in this edition has incorporated the newer terminology of taking precordial leads. He shows his thorough familiarity with the recent American literature and has incorporated much of this knowledge in the monograph, which should be of great value to the Latin American physician interested in utilizing the electrocardiogram in his practice. It is regrettable that the reproductions of the illustrations are poor and that in one or two places the printing of the text is slightly blurred. However, the contents are excellent, the ideas are simply expressed, the material is well organized and the publication accomplishes satisfactorily the purpose for which it was written.

An Introduction to Biophysics By Otto Stuhlman Jr. Ph.D. Professor of Physics University of North Carolina Chapel Hill. Cloth. Price \$4. Pp 375 with illustrations. New York: John Wiley & Sons Inc. London: Chapman & Hall Ltd. 1943.

In spite of the great importance of physics for the understanding of physiologic and therapeutic procedures, relatively little has been done to prepare students of medicine adequately in the physical foundations of physiology and medicine. The present book is a successful attempt in this direction. It deals with the physics of x-rays and radioactivity and discusses the physical principles involved in the microscope and the electron microscope. In addition, physical problems encountered in the study of the functions of the eye and ear are presented. Moreover, a discussion of the physics of surface membranes is given. The presentation of these problems is clear and is supported by numerous diagrams. Unfortunately it is somewhat difficult to the average student of medicine. The reviewer suggests for a further edition an expansion and possibly a more elementary treatment of the problems involved. Topics which could be added should include the physics of temperature regulation, calorimetry and the mechanics of movements. The reviewer would also find it exceedingly useful if a thorough discussion should be given of the various electrical devices used in modern physiology for stimulation of nerves as well as for recording of action potentials.

Synopsis of Diseases of the Skin By Richard L. Sutton M.D. and Richard L. Sutton Jr. M.D. Assistant Professor of Dermatology University of Kansas Medical School. Fabrikoid. Price \$5.00. Pp 481 with 413 illustrations. St. Louis: C.V. Mosby Company. 1942.

The value of synopses and compends of branches of medicine has often been debated. Those initiated in the subject matter may frown on such abbreviated works, though they are popular with students. Judging by the number appearing recently, the publishers find a demand for them now greater than ever. If there must be synopses this one by the Suttons is good. With their large experience at textbook writing they could be depended on to turn out a good one. There is a large amount of material simply and appealingly presented in this pocket-sized book. It is questionable whether some of the uncommon and rare entities such as parapsoriasis, are worth including. The few lines devoted to them give the novice no conception

of them. The pace sacrificed in order to be inclusive could more profitably be given toward enlarging the view of the common and more important everyday diseases. The illustrations are excellent and well chosen. The paper is of a good quality and thin which permits compression into a narrow space. The binding is sturdy.

Nutrition and the War By Geoffrey Bourne D.Sc. Second edition. Cloth. Price \$1.00. Pp 148. New York: Macmillan Company. Cambridge University Press. 1944.

This little book has been designed to help the average person gain some knowledge of foods and nutrition. There is a discussion in general terms of foods as sources of calories, proteins, fats and carbohydrates. The significance of vitamins and minerals is not neglected. An interesting chapter is concerned with nutrition problems under wartime conditions. Approximately half the book is devoted to a listing of the composition of many common foods. The data are provided in terms of numbers of calories and percentage composition in terms of protein, carbohydrate and fat. The data on the vitamins and minerals however are not presented in quantitative terms. The book has a suitable index and should prove useful to those who wish an elementary knowledge of the subject of nutrition.

Contribución al estudio anatómico clínico de las afecciones del endocardio Por el Dr. Manuel Perla Muñoz. Tesis de doctorado. Universidad Nacional de Buenos Aires. Facultad de ciencias médicas. Paper. Pp 363 with 12 illustrations. Buenos Aires 1942.

In a survey of 206 cases of fatal endocarditis the author analyzes the different types of the disease mostly from an etiologic and clinical point of view. The principal conclusion reached is that many patients died because the effort required in their trades was above the capacity of effort imposed by their heart lesions. Accordingly, many lives could have been saved if these patients had had the right occupations for their conditions. It is gratifying to know that the city of Buenos Aires under the inspiration and direction of Professor Bullrich, has started a Service for the social assistance of the cardiac patient."

Diseases of the Nose, Throat and Ear Medical and Surgical. By William Lincoln Ballenger M.D. F.A.C.S. and Howard Charles Ballenger M.D. F.A.C.S. Associate Professor of Otolaryngology Northwestern University School of Medicine Chicago. Eighth edition. Cloth. Price \$12. Pp 975 with 631 illustrations. Philadelphia: Lea & Febiger. 1943.

This is the eighth revised edition of a well established favorite of both students and specialists. It contains a great deal of factual material and numerous enlightening illustrations. The authors have made an earnest effort to keep the work up to date by constantly adding to it material from the current literature. They have had the help furthermore, of a number of associate editors of excellent standing and the result of their combined labors is a worth while textbook of established value.

Las posibilidades de diagnóstico precoz en las osteomielitis agudas de los huesos largos de los niños Por Hector Jorge Sanchez. Tesis de doctorado. Universidad Nacional de Buenos Aires. Facultad de ciencias médicas. Paper. Pp 46 with 13 illustrations. Buenos Aires 1942.

The author describes a new radiologic sign which he interprets as subperiosteal osteoporosis, which would allow diagnoses of osteomyelitis within the first week of the disease. This view is supported by several clinical observations and illustrated by good reproductions of x-ray plates.

Virilización suprarrenal Por el Dr. Enrique B. del Castillo. Tesis de profesorado. Universidad Nacional de Buenos Aires. Facultad de ciencias médicas. Paper. Pp 203 with 49 illustrations. Buenos Aires 1941.

A comprehensive review on the subject with numerous references including important contributions by South American authors. The author himself contributes more than sixty studies, some thoroughly done on patients, children and adults.

Urelografía Por Hector Daniel Muñoz. Tesis de doctorado. Universidad de Buenos Aires. Facultad de ciencias médicas. Paper. Pp 128 with illustrations. Buenos Aires: S.A. Casa Jacobo Peuser Ltda. 1942.

A detailed description of the method and a complete study of the numerous cases observed by the author. Numerous reproductions of x-ray plates and fifty-six references are appended.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ELECTROCARDIOGRAPHIC INTERPRETATION OF BUNDLE BRANCH BLOCK

To the Editor—Fifteen years ago we were taught (I quote from McLeod's *Physiology and Biochemistry* 1922 "Defects of the right or left branch of the A-V bundle give electrocardiograms which closely resemble those described as characteristic of left or right ventricular hypertrophy respectively. In the left bundle branch defects the electrical changes of the right ventricle will impress themselves on the electrocardiogram." In Graybiel and White's book on electrocardiography just the opposite views are expressed. What McLeod calls a right bundle branch block Graybiel and White call a left bundle branch block. Will you please explain?

Angeline Piscitelli, M.D., San Francisco

ANSWER—The change in the point of view concerning the particular bundle branch involved in the electrocardiographic interpretation of bundle branch block records is well expressed in a number of the recent textbooks on electrocardiography. Pardee in the fourth edition (1941) of his book entitled *Clinical Aspects of the Electrocardiogram* (New York: Paul B. Hoeber) states that for many years the localization of the lesion in hearts showing bundle branch block was incorrectly stated because too close an analogy was drawn between the human electrocardiogram and the records obtained from dogs after cutting or crushing the branches of the bundle. Ashman and Hull (*Essentials of Electrocardiography*, second edition, New York: Macmillan Company, 1941) give the following evidences for the newer terminology: "1. In lead I of the exposed human heart, stimulated on the anterior surface of the right ventricle, the chief deflection is upright and the deflection is directed downward upon similar stimulation of the left ventricle. 2. The interval which elapses between the onset of the QRS complex and the beginning of the carotid arterial pulsation averages longer in patients with wide R. If, in such cases, the left ventricle is activated late because of block in the left branch, a late carotid pulsation is obviously to be expected. 3. Chest leads from over the right ventricle indicate early activation of the underlying subepicardial muscle layers in left and late activation in right, BBB, as we have named them. Chest leads from over the left ventricle indicate the reverse. Animal experiments have shown that the method is valid when large differences in times of activation are involved. 4. The cardiac anatomy of the monkey is closer to that of man than the anatomy of the dog. In monkeys, section of one or the other branch produces electrocardiograms which agree with Wilson's terminology. 5. In human hearts, revived by perfusion after death, section of one or the other branch produces the expected picture according to modern terminology. 6. The fact that the human limb lead records can be given a reasonable explanation if Wilson be right, whereas they would be wholly inexplicable if the older terminology were correct, is cogent evidence. 7. Late in rheumatic mitral or in pulmonary stenosis, RBBB, according to Wilson's terminology, is seen not infrequently. In late aortic regurgitation, what he names LBBB may appear. The reverse findings are much rarer. These facts were hard to understand on the basis of the older interpretations. 8. What is now designated RBBB is much more likely than the other type to be unassociated with clinical evidence of heart disease. That the right branch extends for a considerable distance as a single fiber bundle without branching, whereas the left branch subdivides promptly, makes this fact understandable. A small, clinically unimportant lesion may more easily interrupt the right, than the left branch."

ABSORPTION OF GAS THROUGH MIDDLE EAR MUCOSA

To the Editor—Is there any danger of gas being absorbed through the ear of a patient who is without an ear drum as a result of chronic otitis media?

Captain, M. C., A. U. S.

ANSWER—The mucosa of the middle ear is able to absorb both gases and liquids with considerable rapidity, as is evidenced by the rapid absorption of oxygen and nitrogen from the middle ear when the eustachian tube is occluded. The amount of gas that could be absorbed when the drum membrane is absent would depend on the amount that would penetrate to the depth of the ear canal.

DIAGNOSIS AND TREATMENT OF VAGINAL BLEEDING

To the Editor—A woman aged 37 has had irregular vaginal bleeding for twelve years. Sometimes the flow has been continuous for months at a time. Other symptoms are dizziness and stomach distress. The blood pressure is 140/80. The blood Wassermann reaction is negative. She is short in stature, with much fat around the hips and thighs. There is excess hair on the upper lip. Before coming to me she had taken injections of a pituitary extract. She had also had one curettage with only temporary relief from bleeding. I treated her with progesterone in oil seven injections, 2 units each, which reduced the flow but did not stop it. She was sent to a surgeon, who found her uterus normal in size and recommended injections of a combination of chorionic gonadotropin and solution of posterior pituitary. She was given eight injections (a total of 10 cc), this caused her bleeding to be more excessive. I should be glad of advice in the further treatment of this case. M.D., Wisconsin

ANSWER—If the curettement was performed more than two years ago, it should be repeated now. If malignant growth is not found and the bleeding recurs after the curettement or if the curettement was done recently, the patient may be treated with an oral estrogen preparation. A 5 mg tablet of diethylstilbestrol may be taken every night for twenty nights, provided the drug does not produce disagreeable side effects such as nausea or abdominal distress.

In some cases one course of diethylstilbestrol will regulate the menses but in other instances the beneficial effect is only temporary. Nevertheless the treatment is distinctly worth while in this case. Another remedy is the use of testosterone propionate. Twenty-five mg may be given intramuscularly three times a week for four weeks. If the estrogen or androgen produces temporary relief, repeated courses may be given at intervals even for a period of years, but there must be intervals of a few months between the courses of therapy. If the bleeding is not checked or definitely reduced by either the diethylstilbestrol or the testosterone propionate, a hysterectomy should be performed, because irregular bleeding of twelve years' duration not amenable to conservative treatment is serious enough to warrant removal of the uterus.

VENTRICULAR SEPTAL DEFECT AND MARRIAGE

To the Editor—Should matrimony be discouraged for a woman aged 20 with a loud, harsh, widely heard systolic murmur, maximal in the fourth left interspace, typical of a ventricular septal defect, definite thrill over the precordium, and the apex in the fifth left interspace $\frac{1}{2}$ inch to the left of the nipple line? The electrocardiogram showed a rS with a bibasic QRS complex in all leads. An x-ray examination of the chest revealed a general enlargement of the heart of approximately 30 per cent, involving chiefly the left ventricle. There were accentuated vascular markings in both hili. At present the girl is physically fit to perform her secretarial duties and shows no signs of decompensation even after moderate physical exertion. If matrimony should be allowed, would it not be advisable to avoid pregnancy?

M.D., Illinois

ANSWER—It is a moot point as to whether matrimony should be advised in a case like this. If there was an uncomplicated ventricular septal defect, that is, uncomplicated by cardiac enlargement of any significance, one might give permission with the idea of restricting the size of the family. Even so there is the hazard, which is an appreciable one, of subacute bacterial endocarditis. With cardiac enlargement, however, which here seems to be considerable and with accentuated lung hilus shadows, it is obvious that the heart is already under considerable strain and might do badly if exposed to the extra burden of pregnancy. It would seem, therefore, advisable to avoid pregnancy, although marriage otherwise might be compatible with a good many years of survival.

VITAMIN A AND PROGRESSIVE MYOPIA

To the Editor—I should like to have some information regarding the injectable (intramuscular) vitamin A for progressive myopia. Who manufactures it, what is the dosage and what results have been obtained?

Jack Cantor, Lieutenant, M. C., A. U. S.

ANSWER—There is as yet no convincing evidence that vitamin A has any effect in progressive myopia. In most cases of vitamin A deficiency, oral use of a vitamin A concentrate is effective. Probably the only exception to this is in keratomalacia associated with dysentery or some other intestinal disorder which prevents assimilation of vitamin A by the oral route. Such a case was reported by Goldberg and Schlick (Victrola of the Cornea Due to Vitamin A Deficiency, *Arch. Ophthalmol.* 25:122 [Jan.] 1941), who injected 100,000 units of vitamin A in sesame oil intramuscularly daily. The Council on Pharmacy and Chemistry has not accepted any vitamin A preparation for parenteral use, and available evidence affords no proof of the therapeutic value of vitamin A in progressive myopia. It is believed that vitamin A preparations suitable for parenteral administration have been supplied for experimental use by such firms as Abbott Laboratories, S. M. A. Corporation and Winthrop Chemical Company.

RELATIONSHIP BETWEEN VITAMIN B COMPLEX INTAKE AND WORK OUTPUT IN TRAINED SUBJECTS

CLIFFORD J. BARBORKA, MD

ELIOT E. FOLTZ, MD

AND

ANDREW C. ILL, MD

CHICAGO

Factual evidence that is slowly being accumulated both in this country and in Canada, although it is as yet meager, shows that nutritional deficiency disease prevails in many parts of the country.¹ Sebrell² believes that it is no exaggeration to say that at least one third of the American population is eating a diet which is not adequate in all respects. Basing our judgment on the requirements which modern nutritionists consider as optimum nutrition, not mere adequacy, we believe that widespread improvement in health is possible. The evidence of malnutrition is not restricted to low income groups or families on relief but is just as apt to be found in the middle and upper class families.

Although it was suspected that the average American diet might be well below the optimum in certain essential nutrients, there was no means of proof available until the classic publication of Stiebeling and Phipard³ appeared on the diets of employed workers' families, which has been widely quoted. They found only 26 per cent of more than 2,000 workers' families classified as having good diets, the diets of 45 per cent were fair and those of 26 per cent were poor. In respect to these studies, it is well to remember that these were the families of employed workers and not the studies of the unemployed or the families on relief. In addition to this fact, the percentage of poor diets would have been even greater if the statistical data of the diets studied had been measured by the present yardstick of the Food and Nutrition Board's recently recommended daily allowance.

Attention has been called⁴ to a greater need for more thiamine under conditions of increased strain and physical activity. There are thousands of workers in boomtown communities under greater strain and activity than

they have been for years. These people have been moved from their homes into sections not prepared either to house or to feed them properly. Among other factors contributing to poor dietary intake among workers are soft drinks and candy. Many persons arrive at work having had a breakfast of only coffee and a sweet roll. Later they make a widely selected mid-morning and mid-afternoon snack of soft drinks or candy. Large war production plants have been built so fast that feeding facilities are entirely inadequate, and rather low grade restaurants and stands have sprung up of necessity. Industry is beginning to realize the value of optimum intake of nutrients for promoting efficiency and reducing absenteeism.

Keys and Henschel⁵ at the University of Minnesota carefully tested the value of supplementing a United States Army ration with little amounts of available vitamins. It was concluded that supplementation of an adequate diet with additional vitamins serves no useful purpose. We⁶ likewise found no influence on recovery from fatigue or increase in muscular efficiency by parenteral injections of vitamin concentrates in any persons already on an adequate diet.

Such evidence demonstrates the fact that vitamin B complex supplementation added to an already adequate diet has no influence on work output, recovery or other manifestations of physical exertion. Some investigators have contended that work output could be enhanced by the supplementation of the diet with one or more components of the vitamin B complex.⁷ However, it is possible that the subjects of the latter group of investigators might have been on deficient diets, because no exhaustive studies of the subjects' diet or blood and urine determinations for vitamins were carried out. This may account for the apparent discrepancy between these two groups of reports.

Williams, Mason, Wilder and Smith⁸ observed the effect of a thiamine deficient diet on work output. A "chest weight exerciser" was used, but the subjects were not trained. Thus this aspect of the experiment was not well controlled. The diet was not one widely eaten and was deficient only in thiamine. An apparent decrease in work output occurred.

It is well known that many people in the United States are existing on diets low, by our present recommended standards in the vitamin B complex without exhibiting symptoms or signs diagnostic of vitamin deficiency. Does this state of nutrition prevent maximal work output or does the decrease in work output, if it

TABLE 1—Composition in Four Diets

occurs, begin only after the signs and symptoms of vitamin deficiency are well established? In times of war when manpower should be at peak efficiency, this is especially important to know. If a commonly used mildly deficient diet has a detrimental effect on work output it then becomes desirable to know the effect of vitamin supplementations. In an attempt to answer some of these questions this experiment was undertaken.

METHOD

Four medical students were used. They were provided with board and room in a hospital near the laboratory. They were trained from nine months to one year on a normal adequate diet the B complex composition of which is shown in table 1 (diet 1). At the end of this period, they were put on a diet deficient particularly in the vitamin B complex (table 1 diet 2). The corn flakes used in the deficient diets were not restored with thiamine, riboflavin or nicotinic acid and the toast and bread used were unenriched. The butter fat of the cream used was approximately 18 per cent. The calculations of the thiamine and riboflavin content of the food

used was determined by three methods. First, analyses of each of the items of food were made at various times during the past two years. Second, duplicate diets at intervals were simultaneously prepared and sent to the laboratory for analysis. Bread, milk and other liquids were transferred to a tared bowl and the contents mixed until the bread was disintegrated. The meats, vegetables, fruits and salads, which had previously been passed several times through a meat grinder, were then

added. The bowl, which now contained all the constituents of the diet, was again weighed. The composite sample was homogenized in the Waring blender. The entire procedure was carried out as quickly as possible in a cold, darkened room to prevent loss of riboflavin and other vitamins. Determinations of thiamine and riboflavin were made by modifications of the methods of Conner and Straub.⁹ The procedures were standardized by adding known quantities of the vitamins to aliquot portions of the diet. Third, the vitamin content of the diet was calculated by using the averages of recently published data. The result of all three methods of calculation was approximately the same. The caloric, carbohydrate, fat and protein values remained essentially unchanged. The subjects were told that they were being put on a high carbohydrate diet and were unaware that the diet was deficient. A typical day's menu of one of the deficient diets is shown in table 2.

After two months on this regimen, half of the fat calories were taken from their diets and replaced by isocaloric amounts of carbohydrate (diet 3, table 1). This high carbohydrate diet was given in an attempt to precipitate more pronounced symptoms and signs of a vitamin B complex deficiency. After three weeks of this modification they were returned to diet 2 (table 1), supplemented with a yeast concentrate given in a lemon and tomato juice mix, thus preventing its recognition by the subjects. This was diet 4 (table 1). They remained on this diet until the conclusion of the experiment, an interval of four weeks.

The subjects were chosen on the basis of their willingness to cooperate and not on the basis of muscular development, the work of the tests being their only source of physical exercise. The work was done three times each week on an electrodynamic brake bicycle ergometer at the rate of 1,235 kilogrammeters a minute with a pedaling rate of 54 revolutions a minute. The subjects worked to complete fatigue at this rate, rested ten minutes and worked to complete fatigue again. This method of fatiguing the subjects was chosen because it has been demonstrated¹⁰ that the total work output of the double work periods is less variable than the work output of a single work period, and because by this method we are able to study recovery from fatigue. That is, the experiment was so constructed that the second period of work output was almost invariably a fraction of the first, and thus the percentage of recovery from the fatigue following the first period could be calculated. Consequently, we were able to observe the effect of the diets not only on work output but also on recovery from fatigue.

Chart 1—Twenty-four hour thiamine urinary excretion (subject J. A.)

¹⁰ Foltz, E. E., Ivy, A. C. and Barborka, C. J. *The Effect of Work Period in the Study of Fatigue and the Influence of Ca Recovery*. *Am. J. Physiol.* 136: 79-85 (March) 1942.

RESULTS

Thiamine and Riboflavin Levels—In any protracted dietary experiment in which the subjects are not kept under lock and key, their actual intake may vary somewhat from that calculated. That our subjects adhered to their diets reasonably well is shown by charts 1 and 2, data from subject J A, which were characteristic of the entire group. During the depletion period the daily urinary thiamine output dropped to levels of from 5 to 35 micrograms and rose abruptly following supplementation of yeast. The daily urinary riboflavin output fell to levels of from 100 to 200 micrograms daily. The thiamine in whole blood fell somewhat but did not become abnormally low at any time during the experiment (chart 3).

Chart 2—Twenty-four hour riboflavin urinary excretion (subject J A)

Basal Metabolic and Electrocardiographic Studies—Frequent basal metabolic rates and electrocardiograms were taken. In no subject was a significant change in the basal metabolic rate observed. The electrocardiograms of 2 subjects remained unchanged. Those of the other 2 showed an increase in the PR interval of four hundredths of a second. Even with this increase the intervals were not abnormally long. This change persisted throughout the period of yeast supplementation.

Pyruvic Acid Determinations—At frequent intervals blood for pyruvic acid determination was drawn between seven and eight minutes after the second work period. There was no appreciable increase in the blood pyruvic acid following exhaustion during the period of the deficient diets 2 and 3. However, if these values are divided by the number of calories of total work output of corresponding days, a significant change is demon-

Chart 3—Thiamine in whole blood (subject J A)

strated. Chart 4 is a graphic representation of milligrams of blood pyruvic acid produced per calory of work done. Thus it is seen that as the deficiency progressed, that is, up to diet 4, more pyruvic acid was produced per calory of work done, and when the yeast concentrate was added less pyruvic acid per calory was produced.

Work Output—The subjects were trained from nine to twelve months on the adequate diet 1. The work output rose during the first three to four months of the training period until it reached a plateau. This plateau was maintained for six to nine months prior to the institution of the deficient diet 2. There was a definite decrease in the work output shortly after the deficient diet was begun. There was a definite increase in work output following the addition of the yeast concentrate to the deficient diet. This increment was shown by all subjects within forty-eight hours following the yeast supplementation. Within four days, the work output of 1 subject had surpassed that which he had done on a normal diet. The work outputs of the other 3 subjects at the end of four weeks of yeast supplementation had increased to approximately what they had been on the adequate diet.

This is illustrated by chart 5, the graph of subject T N, which is representative of the group. In the upper graph, the top line represents the total work output, the middle line the work output of the first period and the bottom line the work output of the second period. The lower graph represents the percentage of recovery. There was no significant change in the percentage of recovery.

A more detailed consideration of the data obtained on each subject is reported elsewhere by us¹¹.

COMMENT

Four subjects who had been existing on a controlled, adequate diet and who had been trained on the bicycle ergometer for from nine months to one year were placed on a diet deficient principally in the vitamin B complex. During the eighty-two days on the deficient diet the subjects developed irritability, easy fatigability, lack of pep, anorexia and increased leg pain during the work periods, but at no time did they develop any objective physical signs of vitamin B complex deficiency. The twenty-four hour urinary excretion of thiamine and riboflavin dropped to low levels. The blood thiamine remained in the normal range. The blood pyruvic acid following exhaustion was likewise unaffected. However, as the deficiency progressed, the milligrams of pyruvic acid in the blood per calory of work done increased more than 50 per cent. This ratio may prove to be a useful indicator of fairly early vitamin B complex deficiency.

The recommended daily allowances for the various dietary essentials (prescribed by the Food and Nutrition Board of the National Research Council) were set up to serve as a guide for planning adequate nutrition for the civilian population of the United States. We used,

11 Foltz, E. E., Ivy, A. C. and Barborka, C. J. The Influence of Vitamin B Complex Intake on the Work Output of Trained Subjects to be published.

Chart 4—The relationship of blood pyruvic acid to total work output.

therefore, in our adequate controlled diets (during the training period and establishment of the plateau level of work output) 18 mg of thiamine and 27 mg of riboflavin, which is the recommended daily amount of these special nutrients for moderately active men in health.

The deficient diet was composed of common foods, and the menus (example table 2) were such as might be found on the tables of about one third or more of the population of the United States. The deficient diets used (diets 2 and 3, table 1) contained approximately 0.65 mg of thiamine and 0.94 mg of riboflavin, which is about one third of the recommended daily requirement. This deficient diet produced a definite decrease in work output shortly after it was begun, in spite of the lack of physical signs of a deficiency. All of the changes mentioned returned to normal or better following the administration of the yeast concentrate.

Difficult muscular effort such as the civilian, industrial or Army worker must exert, with consequent greater combustion of carbohydrate, should lead to a greater requirement of vitamins. The use of natural foods to bring inadequate diets to the required level is

Chart 5—The graphs here presented of subject T-N are representative of the group. In the upper graph the top line represents the total work output, the middle line the first period work output and the bottom line the second period work output. The lower graph represents the percentage of recovery.

the ideal solution of the problem. Until this plan shall have become workable, discriminate vitamin administration to the civilian or industrial worker on an inadequate diet is a sound policy.

CONCLUSIONS

1 Diets deficient in vitamin B complex in trained subjects decrease work output.

2 Early mild states of malnutrition, with no objective evidence of deficiency disease, do prevent maximal work efficiency.

3 Diets with about one third (0.65 mg of thiamine and 0.94 mg of riboflavin) of the vitamin B complex of the recommended daily requirement do produce subjective symptoms of easy fatigue, irritability, lack of pep, anorexia and increased leg pain during work periods, in spite of the fact that no objective evidence of deficiency disease is present.

4 The ratio of blood pyruvic acid to the total work output increases proportionately as diet deficiency progresses.

5 Subjective symptoms of fatigue, irritability, lack of pep, anorexia and leg pains all disappeared and work output returned to normal or better within a few days following the supplementation of vitamin B complex.

6 Vitamin B complex supplementation added to a vitamin B complex inadequate diet restores work output to efficient levels.

700 North Michigan Avenue

A PRINCIPLE FROM LIVER EFFECTIVE AGAINST SHOCK DUE TO BURNS

PRELIMINARY REPORT

MYRON PRINZMETAL, MD

OSCAR HECHTER, MS

CLARA MARGOLES, MD

AND

GEORGE FEIGEN, BS

LOS ANGELES

Following the development of a method for satisfactorily evaluating therapeutic activity in shock due to burns various agents, some of which have been proposed for the treatment of shock, have been tested. Our purpose in this preliminary report is to present evidence for a principle from liver which has the activity of significantly decreasing the mortality of rats and mice subjected to severe burns and to describe briefly a method for producing standardized burn shock. Evidence is presented which demonstrates that this factor effective against burn shock, which is present in commercial liver extracts prepared to contain the anti-anemia principle, is separate and distinct from the anti-anemia activity.

METHODS

The evaluation of therapeutic agents in shock using the usual shock producing procedures in large laboratory animals is complicated by factors which are difficult to control adequately. It would appear that a satisfactory method should possess the following features. The degree of trauma should be objectively controlled and reproducible; the method should be simple and fast, so that a sufficient number of animals to yield results of statistical significance may be employed under identical conditions; finally, the shock producing procedure should resemble a type of trauma which produces shock in human beings.

During the past year and a half, using 15,000 rats and mice we have developed a satisfactory shock producing procedure which has permitted evaluation of therapeutic activity in shock due to burns. The basis of the method consists in immersing the entire body surface, except for the head and neck, of etherized rats and mice for definite periods of time into a thermostatically controlled water bath set at scalding temperatures. The degree of trauma inflicted by scalding as evidenced by time-mortality curves is a function of the duration of exposure and the temperature of the bath. By lowering the bath temperature or the period of immersion one lowers the degree of trauma; the converse is likewise true. It has been found that when the degree of trauma is too slight an insufficient number of control animals die and therapeutic activity is not measurable. On the other hand, when trauma administered by scalding is too great, then the animals die rapidly irrespective of treatment. We have therefore attempted to use a degree of trauma intermediate between these extremes and have arbitrarily selected the minimal conditions of immersion duration and bath temperature which would kill most of our control animals in a forty-eight hour period. Survival observations were conducted over a forty-eight hour period following scalding. The experiments were terminated at that time to prevent the effects of infection and other secondary disturbances which later become operative following burns from influencing the mortality curves.

The usual conditions for scalding for our animals which have proved to be satisfactory for evaluating therapeutic activity were an immersion duration of 15 seconds at 60°C or at 150°F.

Dr. Yellapragada Subbarow of the Lederle Laboratories, Inc., East Rutherford, N. J., gave invaluable aid. From the Research Laboratory, Cedars of Lebanon Hospital and University of Southern California Medical School. Aided by grants from the Beaumont Trust Fund, the Martha K. Haft Memorial Fund and Messrs. Tom May, Walter Kirschner, M. C. May and Fred Glick.

seconds at 65 C for mice weighing approximately 20 Gm and of 10 or 15 seconds at 75 C for rats weighing approximately 200 Gm. The bath temperature in these experiments varied no more than ± 0.25 degree C and the intervals of immersion are probably accurate to ± 0.5 second. It should be emphasized that the conditions which proved satisfactory for evaluating therapeutic activity in this laboratory may vary for other strains of animals or under different laboratory conditions. In all instances, therefore, these conditions of immersion duration and bath temperature should be experimentally determined before testing therapeutic agents for burn shock.

In general, the experiments were designed so that the treated and control groups of animals had approximately the same distribution of the sexes, were in the same weight range and were derived from the same strain with identical previous histories. The number of animals in each group varied from 20 to 40 in different experiments. Following the start of the experiment the animals were not allowed access to food or water.

The therapeutic activity of various agents was evaluated by comparing the time-mortality curves and the calculated average survival time of treated animals with those of suitable control groups. The survival period following scalding was determined by observing the animals at regular intervals, the dead animals being removed and the time of death noted. All animals dying within thirty minutes after scalding were discarded on the basis that death may not have been due to shock but could have been the result of excessive etherization. All animals alive forty-eight hours after scalding were arbitrarily assigned a survival period of forty-eight hours. Rosenthal has recently described a similar method.¹

After a variable period of time following traumatic scalding, depending on the conditions used, scalded animals show a sharp decrease in skin temperature, exhibit hemoconcentration as evidenced by an increased hemoglobin value, become profoundly asthenic, exhibit dyspnea and finally die. At autopsy, pulmonary congestion was regularly observed and characteristic visceral congestion was usually found while hemorrhagic adrenals and hematuria were irregularly seen.

Further details of our findings will be published elsewhere.

RESULTS EFFECT OF LIVER EXTRACT

Preliminary experiments revealed that three commercial liver extracts, prepared to contain antianemia activity, all appeared to increase significantly the survival time of rats and mice subjected to severe burns. Extensive testing of one of these extracts was then undertaken to establish whether or not this action of

be seen that liver pretreatment definitely decreases the mortality which follows burns and significantly increases the average survival time. This activity of liver against burn shock is highly consistent, as evidenced by the finding that in nineteen consecutive experiments liver extract showed significant activity in 17 instances, in 1 case questionable activity was observed while in only one

A representative experiment showing the time mortality curves of four groups of mice after scalding at 65 C for 10 seconds: black dots curve obtained with 24 mice which received no treatment; the average survival time being 12.8 hours; white squares, the control group of 27 mice receiving 0.2 cc of saline solution; average survival time 11.2 hours; white circles a group of 24 mice receiving 0.2 cc. of a highly purified liver anti-anemia extract 4-149D; average survival time 12.9 hours; black squares curve obtained with 25 mice by pretreatment with 15 unit liver extract; average survival time 28.2 hours. It will be seen that 15 unit liver extract decreases the rate and degree of mortality as compared to the control groups but that highly purified antianemia extract 4-149D is without significant effect. This and other findings demonstrate that the anti-pernicious anemia principle is not the antishock factor.

experiment was liver extract without effect. The accompanying chart shows a typical time-mortality curve, in which 15 unit liver decreases the rate and degree of mortality following scalding burns.

It was of interest to determine whether or not the activity of liver against burn shock was due to the antianemia activity present in the extract. Highly purified extracts of liver antianemia principle prepared by Dr. Yellapragada Subbarow of the Lederle Laboratories by methods described previously² were furnished us. These purified extracts were administered in amounts equivalent to the antianemia activity of the comparatively crude 15 unit liver. The chart shows a representative experiment in which the activity of 15 unit liver is compared to that of a highly purified antianemia liver extract designated as 4-149D. It will be seen that extract 4-149D containing equivalent antianemia activity is inactive while 15 unit liver exhibits its normal activity. It has been found that several other purified extracts of the liver antianemia principle are without significant activity in combating burn shock. These findings clearly indicate that the liver principle effective against shock due to burns is not the antianemia principle.

At the present time, in collaboration with Subbarow and Bohonos of the Lederle Laboratories we are attempting to isolate the active principle. To date, evidence has been obtained which indicates that the activity is (a) relatively thermostable, remaining undiminished after boiling aqueous solutions for twenty minutes, (b) not destroyed by aeration at high temperatures, (c) soluble in water and precipitated from aqueous solution by acetone or ethanol. It may be mentioned that choline, which is present in liver extracts has been tested and has been found inactive.

TABLE 1—Effect of Liver Extract Given One-Half Hour Prior to Scalding on Survival Time of Mice

Treatment	Number of Mice	Number of Mice Survived	Per Cent Difference	Mean Time Survival, Hrs	Standard Error	Per Cent Difference
Lederle 15 unit liver	673	274	+292	24.8	± 1.60	90.6
Saline control	658	63		13.0	± 1.31	

liver extract was consistently reproducible and statistically significant. In these experiments, mice were the test animals. Liver extract containing 15 injectable U S P antianemia units (henceforth referred to as 15 unit liver) was injected intraperitoneally in a dose of 1 cc per hundred grams of body weight one-half hour prior to scalding. The control group received an equivalent volume of saline solution under similar conditions. Table 1 shows the composite data of nineteen experiments on a total of 1,131 mice in which it will

2. Jacobson B. M. and Subbarow Yellapragada. Studies of Principle in Liver Effective in Pernicious Anemia. Recent Advances in Purification of Active Substances. *J. A. M. A.* 116: 367 (Feb. 1) 1941.

It is, of course, important to know whether liver extract is therapeutically effective after the onset of shock. We have found that the intraperitoneal injection of 15 unit liver extract has only occasionally shown such activity. This finding seems most likely due to the fact that large amounts of extraneous tissue constituents are present in all types of commercial liver extracts. Large amounts of such impurities are undoubtedly extremely deleterious to shocked animals. Experiments to determine the activity of liver principle administered after shock will therefore be repeated when more purified extracts are obtained. Likewise, questions related to dosage, route of administration and the like have been deferred until complicating constituents accompanying the antishock activity have been removed from the liver extracts.

The mechanism by which liver extract exerts this antishock activity is unknown. From a priori considera-

trauma in amounts equivalent to 5 per cent of the body weight significantly increases the survival time but that pretreatment with a combination of liver plus salt solution is superior to that with salt solution alone. Further details will be published elsewhere.

OTHER AGENTS

In view of reports that adrenocortical hormones afford protection against certain types of experimental shock,⁴ the activity of desoxycorticosterone acetate and whole adrenal cortex extract against shock due to burns was determined. Neither desoxycorticosterone acetate (25 mg per hundred grams of body weight) given in sesame oil nor adrenal cortex extract (10 cc per hundred grams of body weight) given one-half hour before or following scalding possesses significant antishock activity in rats or mice.

Thiamine hydrochloride, which has been reported to be therapeutically effective in hemorrhagic shock,⁵ failed in our hands in doses of 3 mg per hundred grams of body weight given either before or after scalding to modify the time-mortality curves. Other vitamins such as ascorbic acid, pantothenic acid, nicotinamide and riboflavin given in large doses likewise seemed to be ineffective as regards antishock activity.

The finding that a renal humoral substance, presumably renin, appears in the blood following the induction of experimental shock,⁶ has led to the concept that a renal pressor agent is discharged in response to the hypotension accompanying shock, which then tends to restore the blood pressure toward normal levels. These considerations led us to test the effect of nephrectomy on the survival time of animals shocked by scalding burns. On the basis that the renal homeostatic mechanism is important for combating shock, nephrectomized animals should show definitely decreased resistance to burn shock. However, it was found that nephrectomy does not significantly affect the mortality rate. It therefore appears that the renal homeostatic mechanism, although operative, is not of great importance in influencing mortality following burn shock.

Details will be published elsewhere.

CONCLUSIONS

1 There is a principle in liver which possesses the activity of combating shock due to burns.

2 This antishock factor present in some commercial liver extracts is not identical with the antianemia principle.

EFFECT OF 0.9 PER CENT SOLUTION OF SODIUM CHLORIDE AND OF LIVER PLUS SALT SOLUTION

We have observed that the intraperitoneal administration of 0.9 per cent solution of sodium chloride given in large amounts (5 or 10 per cent body weight) to mice and rats after scalding significantly decreases mortality. Rosenthal³ has independently observed this effect and has shown that the sodium ion is the therapeutic agent. He has further shown that sodium salt solutions administered orally are more effective than the same solution injected intravenously. It was of interest to us to determine the effect of prophylactic administration of large volumes of salt solution and to establish whether or not pretreatment with combined liver plus salt solution was superior to salt solution alone. Table 2 illustrates data on this point. It will be seen that the administration of saline solution one-half hour prior to

3 It appears that the liver principle effective against burn shock is not readily destroyed by heat or oxidation and is precipitated from aqueous solution by acetone and ethanol

4 Nine-tenths per cent solution of sodium chloride, when administered in amounts equivalent to 5 or 10 per cent of the body weight is definitely effective against burn shock when given either after or thirty minutes prior to trauma

5 Pretreatment with liver extract plus large amounts of 0.9 per cent solution of sodium chloride is significantly more effective than salt solution alone

6 The liver factor described and large volumes of salt solution are the only agents which in our hands, have been found to be effective in burn shock, adrenocortical hormones, thiamine hydrochloride and other vitamins being without significant action. The renal pressor system likewise does not prolong the survival time of animals subjected to burn shock

PRIMARY ATYPICAL PNEUMONIA

A REPORT OF TWO HUNDRED CASES AT
FORT EUSTIS, VIRGINIA

CAPTAIN THOMAS A CAMPBELL

CAPTAIN PAUL S STRONG

CAPTAIN GEORGE S GRIER III

AND

LIEUTENANT RAYMOND J LUTZ

MEDICAL CORPS ARMY OF THE UNITED STATES

During the past few years there has been recognized, with increasing frequency, an acute respiratory infection associated with peculiar pulmonary lesions.¹ The vast majority of these cases have occurred among young adults, especially at colleges,² among hospital staffs³ and in army camps.⁴ Inability to isolate a common pathogenic bacterium has led to the use of the term "virus pneumonia." Numerous designations, including "current bronchopneumonia of unusual and undetermined etiology," "atypical pneumonia with leukopenia," "pneumonitis," "acute influenzal pneumonia," "acute diffuse bronchitis" and a variety of other names have been used in reporting similar cases. Actually, none of these terms adequately describe the pathologic picture. It would, we believe, be more nearly correct to call this disease an "acute bronchiolitis with associated atelectasis."

Our purpose in this report is to emphasize the epidemiologic importance of the disease to consider its clinical features with special reference to the roentgenologic findings and to attempt to clarify the involved pathologic processes, omitting entirely the problem of etiology.

Col Daniel L Borden, commanding officer of the Station Hospital, encouraged the writing of this paper. Major Joe M Blumberg of this hospital and Capt Victor Tompkins of the Thirty Third General Hospital made the necropsy report. Dr W Edward Chamberlain and Mr William Taylor of the Temple University School of Medicine made the photographs of the roentgenograms and Dr Beryl Paige of the Columbia University School of Medicine and the Babies Hospital made the photomicrographs.

EPIDEMIOLOGY

It is not at all unlikely that atypical pneumonia has existed for many years and has appeared among the cases described as atypical influenza or grip. Many of the cases of pneumonia encountered during World War I in which it was impossible to find the pneumococcus were probably of this type. Reports of this disease have emanated from all parts of the United States, continental Europe and England. Rates of attack have been variable and difficult to evaluate. It does seem certain that the disease tends to occur both endemically and in minor epidemics. While the increased frequency with which x-ray films have been taken during the past year has undoubtedly accounted for the recognition of many of these cases, there has been an actual increase in the incidence of the disease at this post to an extent to which it is now assuming major epidemic proportions (fig 1). Physicians in neighboring civilian hospitals have also reported a sudden increase of this disease during the past few months.

The effectiveness of a command for training or combat purposes is dependent on the number of men physically fit for duty each day. To indicate the number of men incapacitated because of illness, the term "non-effective rate" was adopted. This term is merely an expression of the number of men sick per thousand strength on the day for which it is calculated. It may also be used to designate the average daily non-effectiveness for a period of more than one day, in which case it denotes the number of men sick per thousand strength during that specified time.

It is clearly seen in table 1 that during the month of September an unusually large number of men (2.2 per thousand strength) were incapacitated for each day of that month because of atypical pneumonia.

The concurrent existence of a large number of infections of the respiratory tract, classified as acute

bronchitis, influenza, grip and nasopharyngitis, at a season when such infections are very common did not justify our inclusion of these cases as a mild form of the disease being described. It was recognized, however, that there did exist at this post, during this same interval of time, a moderate number of cases which

clinically were identical with atypical pneumonia except for the lack of definite abnormalities of the chest and x-ray signs. These were considered cases of bronchiolitis, of probably the same etiology but without the associated atelectasis. The lack of adequate facilities for making etiologic studies led us to omit such cases from our series.

The majority of the reports have dealt with outbreaks almost entirely limited to adolescents and young adults. In view of the several minor epidemics at army posts during prewar times, it is not at all surprising that the disease should become prevalent during a period when mass mobilization is in effect.

Most of the larger outbreaks have occurred during the late fall or early winter months, although sporadic cases have appeared at all seasons. Our cases have followed this general pattern with the trend still upward in the month of October (fig 1).

Very little data were obtained on the incubation period of the disease, but most investigators estimate this period to be about seven to twenty-one days. In 1 of our cases it seemed almost certain that it was fourteen days.

Fig 1—Seasonal incidence of atypical pneumonia at Fort Eustis, Virginia.

While atypical pneumonia does not seem to be highly contagious, prolonged contact, such as occurs in barracks, college dormitories and hospitals, results in a high incidence of the disease. Six of our cases occurred among doctors and nurses who had worked in wards in which the disease was prevalent.

CLINICAL OBSERVATIONS

A gradual onset was noted in the majority of patients and was associated with prodromal symptoms of non-productive cough, low grade fever, muscular aching, malaise, headache and an occasional sore throat. The most common early symptom was a dry cough, which later became productive and often paroxysmal. Substernal soreness, chilly sensations, occasional frank chills and profuse sweats were frequently noted as the infection progressed. Pleuritic pain was uncommon, but substernal soreness on coughing was a common and often distressing symptom. Expiratory grunt and flaring of the alae nasi were absent. With a few exceptions the patients did not demonstrate toxicity, cyanosis or respiratory embarrassment. Soreness of the abdominal muscles due to prolonged coughing was commonly noted. Abdominal pain and tenderness, with occasional nausea and vomiting, were observed in

several instances. One patient displayed such definite abdominal signs that an appendectomy was performed even in the presence of physical signs and x-ray evidence of pneumonia.

The physical examination, on admission, usually revealed that the patient was moderately ill, with

flushed moist skin, injection of the exposed bulbar conjunctivas, coated tongue and slightly inflamed pharynx. The most significant and frequently the only abnormal initial chest signs were suppressed breath sounds. Fine dry crackling rales were often heard at the end of inspiration, particularly after coughing. A small percentage of the patients who showed no abnormality of the chest on admission developed the typical findings after a period of forty-eight to seventy-two hours. Abdominal examination of those patients complaining of gastrointestinal discomfort frequently revealed some superficial tenderness but was without associated spasm.

The laboratory data were of value in differentiating this disease from the bacterial pneumonias. The

TABLE 3—Differential Criteria in Pneumococcal and Atypical Pneumonias

	Pneumococcal	Atypical
Onset	Abrupt	Slow
Cyanosis and dyspnea	Frequent	Rare
Herpes	Frequent	Rare
Pulse rate	Rapid	Normal or only slightly accelerated
Respiratory rate	Accelerated	Normal
Physical signs	Impaired resonance, bronchial breathing	Very slight change in resonance, rare bronchial breathing, frequent rales
Sputum gross	Rusty	Greenish mucoid
Sputum, microscopic and culture	Pneumococci	No predominating organism or occasional higher type of pneumococcus
White blood cell count	Both high	Normal white blood cell count, slightly elevated polymorphonuclear count
Polymorphonuclear count		
X-ray appearance	Dense consolidation	Stringy and mottled type densities
Crisis	Frequent	Rare
Severity	Severe	Mild
Response to sulfonamides	Good	None

majority of the white blood cell counts were normal. A definite leukopenia was rare. There was a tendency for the neutrophilic percentages to be slightly increased, values in the region of 75 to 85 per cent not being infrequent. No predominating pathogenic organisms were found in the sputum except in 3 instances, and these were all pneumococci of higher types which were considered to be without causative significance. A transient albuminuria was noted in those with very high fevers. All blood cultures were sterile.

COURSE

In the presented series only 6 patients were considered to be seriously ill 1 of whom died. The patients rarely looked as sick as their temperatures would indicate. The temperatures on admission ranged from normal to 105 F averaging 102 F and fluctuated widely over twenty-four hour periods. The maximum fever was frequently reached within thirty-six hours after admission and terminated by lysis in about five days regardless of the form of therapy. A few patients continued to have fever for as long as twelve to eighteen days. Pulse and respirations were not accelerated in proportion to the fever.

As the patients improved, the muscular aching, sweats, headache, sore throat and malaise disappeared while the cough became more productive and frequently lasted several days after the temperature reached normal. Spread of the disease process from one lobe to another or from one lung to the other was noted occasionally. Complications were rare but slight pleural effusion was noted in a few cases. One patient developed a rapidly spreading myelitis which proved to be fatal.

TABLE 4—Statistical Summary of Radiographic Findings

Condition	Cases	Per Cent
1 Basilar involvement	162	81
2 Bilateral involvement	44	22
3 Right sided involvement	73	39
4 Left sided involvement	75	39
5 Upper lobe involvement only	2	1
6 Right upper lobe involvement only	22	10.5
7 Left upper lobe involvement only	1	0.5
8 Involvement of left upper and lower lobes only	10	5
9 Involvement of right upper and lower lobes only	4	2
10 Involvement of all lobes	1	0.5
11 Involvement of both lower lobes and right upper	4	2
12 Involvement of upper lobe irrespective of other lobes	30	15
13 Involvement of right lower and left upper lobe		15
14 Presence of pleural fluid (very slight in every instance)	17	8
15 Elevation of diaphragm or shift of mediastinum or both	3	1.5
16 Spread of lung disease after initial film study	12	6
17 Average number of days for film clearing	11.5 days	
18 Case negative on admission and developed density later	1	0.5

The average period of hospitalization was twelve days, but this high figure is partially due to the necessity of keeping these patients in the hospital until they are ready to assume full military duty.

THERAPY

It has been shown conclusively that sulfathiazole and sulfanilamide did not alter the course of the disease in any way. In this series the average duration of fever for all 200 cases was 5.1 days, whereas in the 98 cases in which a sulfonamide compound was given the fever lasted 5.8 days and in the 102 cases in which symptomatic treatment was given the average duration of the fever was 4.4 days. Routine therapy was supportive in nature and included bed rest, adequate fluids, antipyretics and sedatives. A persistent cough often responded favorably to steam inhalations and expectorants. The oxygen tent was of value for those patients who were cyanotic or dyspneic.

ROENTGENOLOGIC ASPECTS

An analysis of the roentgenograms in this series of 200 cases of atypical pneumonia demonstrated that 81 per cent of the pulmonary lesions were basilar, that 39 per cent were located on the right side while a similar percentage was seen on the left and that 11 per

cent of the cases showed involvement of the right upper lobe and in 5 instances were misdiagnosed as pulmonary tuberculosis (fig 3). Differentiation between pulmonary tuberculosis and atypical pneumonia could be made only by repeated progress film studies and sputum examinations. In 1 of Kneeland and Smetana's cases³ pneumothorax had been instituted before the true nature of the lesion in the upper lobe was appreciated.

Although in all our cases initial roentgenograms were made in only 100 were adequate progress film studies done. Of these 100 cases it was found that 57 per cent had cleared radiographically at the end of ten days, 85 per cent in twenty days and the remaining 15 per cent in the ensuing twenty day period.

Since 81 per cent of these cases demonstrated basilar disease, detailed description will be confined to this type of involvement (fig 3). Careful examination of the basilar shadows revealed a streaking type of density which radiated downward from the lung root and extended outward over the leaf of the diaphragm. These shadows conformed to the general distribution of the bronchi. Superimposed on the stringy density was a mottled type of shadow which occurred in any part of the chest but was most commonly seen at the right cardiophrenic angle at or below the lung roots or along the left border of the heart. Kornblum and Reimann, in reference to a similar epidemic, described these streaking densities radiating from the lung roots and used this finding as an x-ray criterion for diagnosis of tracheobronchitis. The underlying disorder in our 200 patients was in accord with this interpretation, but all roentgenograms demonstrated superimposed mottled densities. The mottled densities were interpreted as a lobular form of atelectasis based on a definite mechanical factor—the complete block of the smaller bronchi and bronchioles by collected exudate and swollen epithelium. It was thought that the stringy type of densities represented a combination of

Fig 2 (case 1)—Basilar stringy and mottled density seen in 81 per cent of our cases. The radiating stringy densities represent diseased bronchi and bronchioles. The hazy mottled density represents atelectatic lung. Note the platelike areas of atelectasis with associated elevation of the right leaf of the diaphragm.

Fig 3.—Patchy atelectasis of the right upper lobe resembling pulmonary tuberculosis.

3 Kornblum, Karl and Reimann, Hobart A. The Roentgenological Aspects of an Epidemic of Acute Respiratory Tract Infection. *Am J Roentgenol* 44:333 (Sept.) 1940.

exudation within bronchi and bronchioles, swollen bronchial and bronchiolar epithelial lining, and peribronchial and peribronchiolar cellular infiltration (fig 7). The majority of the soldiers in question were ambulatory during the days prior to their initial x-ray examination and because of the dependent drainage of

Fig. 1—A, the homogeneous density in the right upper lobe has the appearance of a lobar pneumonia. However, the decided right sided shift of the trachea and heart with elevation of the diaphragm reveals its true atelectatic nature. B, same case seventeen days later demonstrates complete reexpansion of the right lung. The mediastinal structures and the right leaf of the diaphragm have assumed their normal positions.

exudate the basilar portions of the lung fields would be the part most frequently involved. This conception was verified by the fact that 81 per cent of these cases demonstrated basilar pulmonary disease. Snow and Cassasa⁶ in their reviews of bronchiolitis in children and influenza in adults stressed the importance of dependent drainage of exudate in the mechanism of basilar atelectasis.

The fact that 19 per cent of these cases showed a shift of the mediastinal structures, or an elevation of the diaphragm toward the site of lung involvement, gave further substantiation to the diagnosis of atelectasis (fig 4). On rare occasions a complete lobe became atelectatic (fig 4), and in these roentgenograms the shift of the mediastinum and the elevation of the diaphragm was pronounced. The collapsed lobe often simulated lobar pneumonia, but the diminished volume of the involved lobe, narrowing of the rib interspaces, shift of the mediastinum and elevation of the diaphragm revealed its true atelectatic nature.

A distinctive feature of this disease was the variability of the pulmonary involvement. In many cases the mottled densities were seen to appear and disappear over night. The intermittent obstruction of the smaller bronchi and bronchioles was thought to be responsible for the transient pulmonary changes, and this may have accounted for the negative x-ray appearances when physical signs were present beforehand. Snow and Cassasa⁷ have conclusively shown that bronchiolitis in children will give the pathologic appearance of atelectasis and emphysema, with the latter being the prominent radiographic finding. In children, air is allowed to enter the alveolus through the diseased bronchiole but is not permitted to escape. In effect, the involved bronchiole acts as a ball valve which holds the alveolus in a state of constant inflation. In contrast, the adult cases of bronchiolitis, such as those

being described, demonstrated complete bronchial block with associated absorption of alveolar air.

One striking feature that was quite apparent in the majority of cases was the presence of horizontal linear densities overlying either diaphragm (fig 5). This finding was usually discovered after considerable clearing of the basilar shadows. These band densities had the appearance of the platelike atelectasis described by Fleischer and his associates,⁸ who proved conclusively, by correlation of postmortem teleoroentgenograms with gross and microscopic studies, that the band shaped horizontal basilar densities represented atelectatic lung.

It is remarkable to note that in only 6 per cent of these patients radiographic evidence of pleural fluid developed, and in these instances the amount of fluid was insignificant (slight obliteration of either costophrenic angle).

On review of the case illustrated in figure 6 it is noted that the density in the right lower lobe had not changed in a period of forty-six days. A bronchogram made with iodized oil at the end of that time not only revealed atelectasis but also demonstrated localized fusiform bronchiectasis. It is universally agreed that unrelieved atelectasis, as well as an acute bronchiolitis, may cause bronchiectasis. With these facts in mind, one can readily see that bronchiectasis could be a serious complication in the 15 per cent of chests which failed to clear after twenty days of hospitalization. (This phase of the problem, we believe, would warrant further investigation.)

An unusual complication encountered in 6 cases was the presence of multiple rib fractures, apparently the result of prolonged severe coughing. These fractures were usually overlooked in the initial roentgenograms but became apparent on subsequent studies, which demonstrated callus formation.

A TYPICAL CASE

CASE 1—G. H. L., a white soldier aged 21, was well until September 24, when a nonproductive cough developed. Two days later he began to have fever and generalized muscular aching, which continued until his admission on September 28.

The principal physical findings on admission consisted of slight inflammation of the pharynx, moderate enlargement of the right tonsil, decreased breath sounds at the base of the right lung posteriorly and a few rales over the same area. The admission temperature and the pulse and respiratory rates were 103.2 F, 112 and 28 respectively.

The white blood cell count was 6,500 with 70 per cent polymorphonuclears. A roentgenogram of the chest taken on September 28 revealed both mottled and stringy densities at the base of the right lung and elevation of the diaphragm on that side (fig 2).

General supportive measures were instituted on admission.

In addition, sulfathiazole was given for the first three days but, conforming with our experience, no beneficial effect was noted. The course of the disease was uncomplicated. Post-

Fig. 3—Complete collapse of the right upper lobe is noted with platelike areas of atelectasis overlying each leaf of the diaphragm. The mediastinal structures have been pulled to the right side.

signs in the chest persisted up until the eighteenth day of hospitalization. The patient was discharged to full duty on the nineteenth hospital day.

REPORT OF THE FATAL CASE

CASE 2—R. W. S., a soldier aged 24, was admitted to the medical service of the Station Hospital Fort Eustis, Virginia on Sept 15 1942. His chief complaints were those of cough, pain in the chest and fever of two days' duration. The temperature was 102 F, the pulse rate was 112 and the respiratory rate was 22. The patient did not appear acutely or seriously ill. A few moist rales were noted over the middle lobe of the right lung. The remainder of the physical examination was negative.

The white blood cell count was 6,750 per cubic millimeter, with 80 per cent polymorphonuclear leukocytes. The urine was normal. Smears and culture of the sputum showed no pneumococci. A roentgenogram taken September 16, showed a diffuse area of density spread throughout the right lung field, most pronounced along the lower portion of the right upper lobe. Another film taken on September 23 revealed considerable spread of the process in the right lung with some involvement of the left lung. A blood culture was sterile after twenty-two hours' incubation.

For the first four days in the hospital the patient received symptomatic treatment. His temperature during this period varied from 99 to 104 F although at no time did he seem seriously ill. On September 19 his temperature rose to 105 F and he was started on sulfathiazole medication with an initial dose of 2 Gm, followed by 2 Gm in two hours and then 1 Gm every four hours. There was little response to the drug as far as the febrile course was concerned although the patient seemed clinically improved.

On September 22, the seventh day in the hospital, the patient seemed more acutely ill and began to complain of transient pains and numbness in his feet. Physical examination which included a careful neurologic examination failed to reveal anything to account for these changes. The following morning the patient was unable to move his legs. Examination at that time revealed a flaccid paralysis of the lower extremities with loss of sensation extending up as high as the second thoracic vertebra. There was slight nuchal rigidity but the Kernig and Brudzinski signs were negative. No other pathologic reflexes were noted. His subsequent clinical course was characterized by rapid progression of the paralysis which reached the upper extremities and diaphragm twelve hours after its onset. Lucid periods alternated with periods of considerable confusion. Lumbar puncture revealed cloudy fluid under increased pressure with 2,000 cells 90 per cent of which were polymorphonuclears, increased protein, a normal sugar and a negative smear and culture. Associated with the rapid spread of the paralysis the temperature rose progressively, and with the approach of 108 F, respirations ceased.

POSTMORTEM EXAMINATION

Gross—The body was well developed but rather thin, measuring 69 inches (175 cm) and weighing about 65 Kg. There was a linear scratch over the right aspect of the right side of the abdomen measuring 12 cm in length and a skin puncture in the midlumbar region. The chest was symmetrical. There was no peripheral lymphadenopathy.

The head was ovoid, hair on the head was abundant, dentition was good, there was a small amount of mucoid fluid in the mouth. Hazel irises were surrounded by round, regular pupils, each 0.6 cm in diameter.

The peritoneal cavity contained no excess free fluid. The heart appeared slightly dilated. The epicardial fat was abundant. The maximal transverse diameter in situ was 16 cm. The thymus measured 3 by 4 cm.

The pleural cavity contained about 200 cc of bloody fluid. The lungs filled the available space.

The heart weighed 450 Gm and had a small amount of adherent fat. The auricles appeared normal, measuring 2 to

3 mm in thickness. The circumferential measurement of the tricuspid valve was 11.5 cm. The pulmonary valve measured 8.25 cm and was normal otherwise. The right ventricle measured 6 mm in thickness. The left auricle measured 1 mm and was normal. The mitral valve in circumferential measurement was 9.5 cm. The leaflets contained no vegetations. The right ventricle had an average thickness of 12 mm. The mus-

Fig 6—A initial film study done on July 5, 1942 demonstrates a dense horizontal band of atelectasis overlying the right heart or the diaphragm. B studies made with iodized oil on August 20 after the right lower lung field failed to re-aerate demonstrates the crowded lower and middle lobe bronchi typical of atelectasis. Note the bronchiectasis. C re-aeration is shown on a progress study done on September 11. Note the iodized oil remaining in one of the bronchiectatic bronchi of the right lower lobe.

cles were normal. The aorta contained a few early formed atheromatous plaques, some of which appeared to encroach around the coronary openings.

The right lung weighed 1,130 Gm. The pleura was smooth, shiny and translucent. The pleural surface displayed a quilted effect. Small (1 to 3 cm in diameter) pink aerated crepitant segments of tissue were slightly elevated above dark red rubbery tissue. On section the major portion of all lobes presented a bloody surface which was fairly dry when scraped. There was no spontaneous fluid or foam flow. On pressure some pink thin foam welled from minor bronchi. The cut surface varied considerably in color. Salmon pink alternated with dark red in scattered fashion the foci of each being poorly demarcated. Near the hilar portion most of the lung was dark red. The pink tissue was crepitant and visibly aerated. The dark tissue was noncrepitant but soft and spongy. Finger pressure produced a pit here. The absence of tractability and of firmness was remarkable in the consolidated portions. A very few firm nodular foci were palpated. These did not account for the extensive lack of aeration. The bronchial mucosa was reddened, velvet and thickened. The bronchial tree contained thin bloody fluid. The pulmonary veins and arteries were patent throughout. The lymph nodes of the bronchial and

peribronchial group were enlarged, moderately firm and dark brownish red on section

The left lung weighed 660 Gm. The pleural surface presented a number of confluent superficial hemorrhages. The lower lobe was completely subcrepitant but remained elastic. It was reduced in volume. The upper lobe near the margin

Fig. 7—Severe bronchitis with peribronchial infiltration. Note the intrabronchial cellular exudate.

of the upper lobe contained air and was crepitant. On section the upper lobe was dull red and uniform. The lower lobe was salmon pink. The inferior lobe, besides the general doughy feel, presented a central focus of ill defined firmness roughly 2 cm in diameter. The bronchial tree contained thin bloody fluid, the bronchial walls were injected. The upper lobe, particularly the anterior lappet, was well aerated.

The liver weighed 1,950 Gm. Throughout it showed a rather normal architecture and contained slight yellow focal areas, otherwise it appeared normal throughout, it was moderately congested. A small Riedel lobe was present.

The gallbladder contained dark green bile fluid. On pressure bile was expressed through the ampulla of Vater.

The spleen weighed 240 Gm and was purplish red and soft. On section it was mottled, fibrous and a mottled reddish brown. It appeared moderately congested, otherwise it was normal.

The right adrenal weighed 11 Gm, the left adrenal 8 Gm.

The right kidney weighed 300 Gm, was reddish purple and appeared normal. The capsule stripped with ease. The left kidney weighed 300 Gm and appeared similar to the right kidney.

There were small punctate petechial hemorrhages on the stomach.

The pancreas weighed 135 Gm and appeared fibrous in structure.

The bladder contained about 20 cc of cloudy straw colored fluid. The ureteral orifices were patent and the trigone appeared normal.

The brain weighed 1,620 Gm. The brain grossly showed a rather definite generalized hyperemia and what appeared to be edema of the piamatral areas. The sphenoid sinuses were free of pus.

The entire spinal cord showed a moderate degree of hyperemia. The lumbosacral region was moderately yellow, appearing with small attached plaques adhering to the arachnoid-pia area.

Microscopic—The important changes in the lungs were those of bronchitis and peribronchitis, interstitial pneumonitis and atelectasis. The entire process was unusual.

The major bronchi showed sloughing of the epithelium. The mucosa was moderately edematous and diffusely infiltrated with lymphocytes, occasional plasma cells and a moderate

number of well preserved neutrophils. The vessels were engorged. The mucus glands appeared normal. In the smaller bronchi there was a similar process with the lumen partly occupied by exudate, but there were conspicuous peribronchial accumulations of lymphocytes and plasma cells. These accumulations in some sites presented the picture of hypertrophied peribronchial lymphoid apparatus, in other sites, however, they were more typically inflammatory. Not all bronchi were involved, as could be seen in the aerated anterior margin of the left upper lobe. Nor was the process uniform as regards the extent of mucosal and peribronchial changes. For instance in the left upper lobe one section showed peribronchial change with relatively little mucosal inflammation. The contents of the bronchial tree were usually purulent with very little mucus mixed with it. Sections from the right lower lobe showed a general decrease in the size of the alveoli. This process occurred either associated with thickening of the alveolar wall or in its absence. The alveoli which had thickened walls contained rafts of mononuclear cells, some in epithelium-like alignment. Some of these cells had phagocytic properties, having engulfed nuclear remains or blood pigment. The thickening of alveolar walls was accompanied by edema and a variable amount of lymphocyte and plasma cell accumulation (figs 7, 8 and 9).

There were a few changes in isolated foci in which organizing fibrinopurulent plugs occupied alveolar spaces and a few sites of intra-alveolar fluid and granulocytes indicating bronchopneumonia, old and recent. This was a minor feature. A single focus of necrosis was visible in the lung parenchyma at a place where bronchopneumonia as well as interstitial pneumonitis was present. There was no visible vascular lesion to account for this, however. The interstitial cords of the spleen contained an increased number of cells, among which were many granulocytes. There was some vacuolization of the centrilobular liver cells, slightly decreased cortical lipid of the adrenals and slight parenchymatous degeneration of the tubules of the kidneys.

Section through a temporal horn of the cerebrum including the hippocampus showed a small focus of perivascular edema and granulocyte infiltration. The ganglion cells appeared well preserved. This suggested that the inflammatory process was very recent here.

Section of the basal ganglia showed an outer portion of the lentiform nucleus (putamen), caudate nucleus, claustrum and

Fig. 8—Alveolar collapse with interstitial round cell infiltration.

cortex of the insula and demonstrated only slight pial edema with a rare lymphocyte and neutrophil in the pia both on the cortical surface and in the reflections along the major vessels.

Section of the cerebellum showing cerebellar folia and emboliform and dentate nuclei revealed no parenchymal change. The meninges were edematous and contained a few granulocytes, lymphocytes and plasma cells.

Section of the hypothalamus which contained a portion of pituitary stalk, demonstrated no noteworthy changes other than a moderate number of lymphocytes about some of the larger vessels.

Sections of the cord from the cervical and lumbar regions may be described together. The changes were minimal con-

Fig 9—Extensive interstitial round cell infiltration and well defined atelectasis as seen under low power

sisting of pial edema with slight infiltration with lymphocytes and neutrophils. Levels of the eighth and tenth thoracic vertebrae presented an entirely different picture. Here there was extensive perivascular necrosis, edema and neutrophil infiltration with deposition of fibrin. Some vessels were occluded by fibrin thrombi. The process was so extensive as fairly to constitute small abscesses. The change involved white as well as gray matter and could be traced in 1 instance to a peripheral nerve root where the necrosis occurred also about the central vessel. There was some meningitis characterized by accumulation of neutrophils. There was no doubt, however, that this was secondary to the changes within the cord.

PATHOLOGIC DIAGNOSIS

- 1 Bronchitis, bronchiolitis, peribronchitis and peribronchiolitis
- 2 Interstitial pneumonitis, etiology unknown
- 3 Atelectasis, secondary to bronchiolitis and peribronchiolitis
- 4 Bronchopneumonia, old and recent
- 5 Encephalitis, local, acute, secondary to foregoing
- 6 Purulent myelitis involving lower thoracic segments, etiology unknown
- 7 Meningitis, acute, slight, secondary to foregoing

COMMENT

A disease which, because of its prolonged period of hospitalization, gives rise to a great loss of man days becomes of tremendous military importance when it is prevalent. The rapidly mounting incidence of atypical pneumonia at this post led to the preparation of this brief review of 200 unselected cases. The symptoms and physical signs have been dealt with hurriedly because this phase of the disease has been well described in the current literature. Special emphasis has been given to the physiopathologic changes of atypical pneumonia: roentgenography, studies with iodized oil and the one postmortem examination being used as aids. No final conclusions can be drawn from a single case. Deaths from this disease are rare. The fatal case presented all the clinical features that were noted in the other cases in this series as well as similar radiographic changes. The studies with iodized oil and the microscopic anatomy of the lungs served to confirm the

roentgenologic belief that atelectasis rather than true pneumonia was the underlying pathologic condition and accounted for the mottled type of density seen in the x-ray film. The primary process was believed to be a peribronchitis, peribronchiolitis, bronchitis and bronchiolitis with swelling of the bronchial epithelium and exudation into the bronchi and bronchioles with resultant occlusion and absorption of air.

The similarity between the lesions of atypical pneumonia and those of pulmonary tuberculosis has led in some instances to incorrect diagnoses which have brought about unfortunate results. Not only have artificial pneumothoraces been induced but patients have been discharged from the Army with the erroneous diagnosis of pulmonary tuberculosis. At a time when the need for manpower is so critical errors such as this are to be strictly avoided. Serial roentgenograms and repeated examination of sputum are indicated in cases in which there is doubt concerning the diagnosis.

The differentiation from bacterial pneumonia, whether of lobar or of lobular type, should in the majority of instances cause no difficulty. Among the severely ill patients this trouble may be encountered as it was on 2 occasions in our series. It is a good policy to give the sulfonamides when there is doubt.

While spread of the disease process from one lobe to another or from one lung to the other was noted occasionally there were no true relapses. As far as it was possible to ascertain there were no readmissions of any of these patients with a second attack of the disease, although our observations were limited by the relatively short training period.

SUMMARY

- 1 A study of 200 unselected cases of atypical pneumonia occurring during an epidemic of this disease at Fort Eustis, Virginia, was made.
- 2 The disease is a self-limited type of pulmonary infection with mild and infrequent complications.
- 3 The epidemiologic aspects of the disease and its high noneffective rate are important to the military service.
- 4 The pathologic condition underlying the bizarre roentgenographic changes is that of bronchitis, bronchiolitis, peribronchitis and peribronchiolitis with associated atelectasis caused by mechanical obstruction of the bronchi and bronchioles and does not represent a true pneumonia.
- 5 Eleven per cent of cases present apical lesions which may be confused with pulmonary tuberculosis unless progress film studies are made.
- 6 Treatment with sulfathiazole and sulfanilamide is without effect on the clinical course of the disease.
- 7 A fatal case with complication of the central nervous system was examined post mortem.

No Mechanism to Oxidize Urate—Man and the ape are unique in the precise steps of purine metabolism and occupy an intermediary position between reptiles and certain mammals in so far as the metabolism of nitrogenous products is concerned. The amino-nitrogen and pyrimidin-nitrogen waste is excreted as urea while the purine nitrogen is excreted as urate because no enzyme is present to oxidize urate to allantoin. If man were endowed with a mechanism which enabled him to oxidize urate, gout would not be possible or else it would manifest itself as a different clinical and chemical disturbance.—Talbot John H. Infectious diseases often appear in epidemic proportions under wartime conditions when it becomes necessary to gather large bodies of troops into crowded quarters. Such conditions are particularly favorable to the spread of the air borne infectious diseases of the respiratory tract. While experimental work with aerosols apparently offers promising prospects for controlling droplet infections, effective techniques have not as yet been perfected for employing these substances on a large scale. Several recent reports¹ have appeared, on the other hand, showing that small doses of sulfanilamide, given over prolonged periods, will prevent rheu-

Chart 1—Weekly case rate of scarlet fever in the radio school and pier personnel before and after administration of sulfadiazine

matic subjects from having hemolytic streptococcus infections of the respiratory tract and thereby save them from recurrences of rheumatic fever. In addition, reports have appeared indicating that the sulfonamide compounds have been used effectively to protect scarlet fever contacts² and prevent meningococcal,³ gonococcal and chancroidal infections.⁴ It therefore seemed probable that the sulfonamide compounds might be similarly

used to control epidemics of hemolytic streptococcus infections among normal men. This communication is a report on the use of sulfadiazine in controlling an outbreak of scarlet fever at a United States naval station.

EPIDEMIOLOGIC SITUATION

The personnel at this station was housed on a large pier and during the period of investigation numbered several thousand. It was divided into two groups: (1) students in a radio school and (2) transients. The former slept and messed on the pier but spent their days in classes held in a building a few blocks away. The radio school students were further divided into four classes, each of which lived on the pier four months; a new class started its schooling the middle of each month. The transient group, termed the pier personnel, was about four times the size that of the radio school. These men, coming from many places, remained at this station from a few hours to several weeks while awaiting assignment to duty elsewhere. The weekly turnover among this group was approximately equal to two thirds of the capacity of the pier. The two groups were lodged together under the same roof, slept in double decker beds and messed in the same hall.

METHODS OF STUDY

All patients with scarlet fever or suspected scarlet fever were admitted either to the U S Naval Hospital, Brooklyn, or to the Hospital of the Rockefeller Institute for medical care. Only unquestionable cases of scarlet fever are considered in this paper. Nose and throat cultures were taken on all patients admitted to the Hospital of the Rockefeller Institute, and through the courtesy of Lieut Comdr A F Coburn throat cultures were obtained from most of the patients admitted to the Brooklyn institution. All were submitted to similar bacteriologic analysis at the Hospital of the Rockefeller Institute.

Throat culture surveys were also made at intervals during the study to determine the carrier rate for hemolytic streptococci at the station. In making these cultures, particular care was taken to swab both tonsillar areas and the posterior pharyngeal wall. The swabs were then immediately wiped on fresh 5 per cent sheep blood agar plates. These plates were brought to the laboratory, streaked properly and incubated aerobically for twenty-four to thirty hours at 37 C. Representatives of all suspected colonies were transferred to fresh blood agar plates or to broth for further identification. The hemolytic streptococci were grouped and typed by the precipitin methods described by Lancefield.⁵

Determinations of blood sulfadiazine concentrations were made with fresh oxalated samples of venous blood according to the method of Bratton and Marshall.⁶

DESCRIPTION OF EPIDEMIC AND RESULTS
OF STUDIES

The first case of scarlet fever to appear at this station in the fall of 1942 occurred on September 28. During October only a few additional cases were reported, the number were about equally distributed between the radio school and the pier personnel. During the first two weeks in November, however, the incidence of scarlet fever increased sharply in both groups, as indicated in chart 1. By November 20 the number of cases in the radio school had reached a level of 10 a week, with a slightly higher incidence among the pier personnel.

The hemolytic streptococci from all of the patients admitted to the hospital in the early part of November were identified as group A type 19. With a single type causing all the cases it was apparent that the existing conditions were favorable for developing and perpetuat-

ing an epidemic. It soon became evident also that the incidence of scarlet fever in the radio school, which consisted of the more permanent population, was proportionately higher than that among the pier personnel. With these facts in mind it seemed possible that if the disease could be controlled in the radio school the incidence among the pier personnel might also decrease, since this population was mostly transient.

On November 20, therefore, as a prophylactic measure, the entire personnel of the radio school was started on 0.5 Gm of sulfadiazine twice a day. The drug was given at 8 a. m. and 4 p. m. and was continued for a period of thirty-two days, through December 22. The results were striking (chart 1). During the first week after sulfadiazine was started the incidence dropped to 4 cases a week, and during the next three weeks only 5 new cases of scarlet fever appeared among this group.

For three weeks after sulfadiazine was begun in the radio school, the incidence of scarlet fever among the pier personnel, on the other hand, remained high. For this reason the pier personnel was started, December 11,

on prophylactic doses of sulfadiazine 1 Gm daily, given at 8 o'clock each morning, because it was not possible to divide the daily dose as was being done at the radio school. The drug was continued for 12 days through December 22, during the first seven days the population at the station was stabilized as far as conditions would permit. The effects, as shown in chart 1, were even more striking than had been observed in the radio school.

A total of 95 cases of scarlet fever occurred at this station between September 28 and December 18. Satisfactory throat cultures were obtained from 72 patients, of which 71 were positive for hemolytic streptococci group A type 19 and 1 for type 5. From December 18 through January 8, the end of the period of observation, no new cases of scarlet fever appeared, although sulfadiazine was discontinued in both groups on December 22.

* The radio school received sulfadiazine 0.5 Gm twice a day from November 20 through December 22. The pier personnel received sulfadiazine 1 Gm daily from December 11 through December 22.

ing an epidemic. It soon became evident also that the incidence of scarlet fever in the radio school, which consisted of the more permanent population, was proportionately higher than that among the pier personnel. With these facts in mind it seemed possible that if the disease could be controlled in the radio school the incidence among the pier personnel might also decrease, since this population was mostly transient.

On November 20, therefore, as a prophylactic measure, the entire personnel of the radio school was started on 0.5 Gm of sulfadiazine twice a day. The drug was given at 8 a. m. and 4 p. m. and was continued for a period of thirty-two days, through December 22. The results were striking (chart 1). During the first week after sulfadiazine was started the incidence dropped to 4 cases a week, and during the next three weeks only 5 new cases of scarlet fever appeared among this group.

For three weeks after sulfadiazine was begun in the radio school, the incidence of scarlet fever among the pier personnel, on the other hand, remained high. For this reason the pier personnel was started, December 11,

This complete absence of scarlet fever following the withdrawal of sulfadiazine was unexpected, particularly when the results of the throat culture surveys are considered. A summary of these surveys, made on both the radio school and pier personnel, is given in table 1. It is evident from this table that, although both the group A and type 19 carrier rates decreased in the radio school during the period of sulfadiazine prophylaxis, the rates were still rather high when the drug was discontinued, furthermore, surveys on the pier personnel before and after sulfadiazine medication revealed no significant drop in either the group A or the type 19 carrier rate.

A factor which may have played a significant part in delaying the recurrence of scarlet fever following the withdrawal of sulfadiazine was the intervening Christmas and New Years holidays. At this time, because many of the men were given short periods of leave, a number of the carriers and susceptible persons were temporarily removed from the epidemic area. A favorable effect of holiday periods on epidemics of strepto-

coccic respiratory infections has been noted previously by Thomson and Glazebrook.⁷

From table 1 it is apparent that carriers of type 6 hemolytic streptococci were also prevalent. With a carrier rate of almost 10 per cent in the radio school, it seems improbable that this strain failed to induce

while the number with nonrespiratory complaints remained essentially the same. The average number of daily sick calls made for respiratory and nonrespiratory complaints at the radio school and pier, both before and during sulfadiazine administration, are shown in table 2. The smaller number of sick calls for respiratory complaints among the pier personnel during the three weeks before this group was started on sulfadiazine may have been due to a decrease in infectious contacts from the radio school personnel.

Sulfanilamide has been employed almost exclusively by the investigators reporting on the use of sulfonamide compounds for the prevention of rheumatic fever. Only Hansen, Platou and Dwan¹ report giving several of their patients sulfadiazine for short periods, but they make no mention of the blood concentrations of the drug. In those instances in which sulfanilamide has been employed, the dose has varied between 0.6 Gm and 3 Gm daily and the great majority of the patients were under 16 years of age. In the present study the blood concentration of sulfadiazine was determined on 50 men from the radio school. The blood was taken about six hours after the morning dose on the twelfth day after the drug was begun. The distribution of the blood levels of the free drug is shown in chart 3. The

Chart 2—Effect of sulfadiazine administration on daily sick calls

TABLE 2—Average Daily Sick Calls Before and During Sulfadiazine Prophylaxis

Periods	Radio School Personnel		Pier Personnel	
	Nonrespiratory Complaints	Respiratory Complaints	Nonrespiratory Complaints	Respiratory Complaints
Before sulfadiazine prophylaxis	14.5	50.5	50.2	61.6
During sulfadiazine prophylaxis	16.0	29.0	48.0	29.1

respiratory infections. Despite the fact that laboratory tests⁸ showed the type 6 strain to be as potent a producer of erythrogenic toxin as the type 19, none of the cases of scarlet fever cultured during the epidemic were due to this strain. Just what role it may have played in causing pharyngitis and tonsillitis was not ascertained.

When the striking effects of sulfadiazine in lowering the incidence of scarlet fever were observed, it was of considerable interest to determine its influence on the number of daily sick calls. Since the final diagnosis is not recorded at sick call, these data were compiled only on the basis of complaints. In chart 2 the complaints for both the pier and the radio school personnel have been divided into respiratory and nonrespiratory categories and the number of each charted daily with

Chart 3—Concentration of free sulfadiazine in the blood of 50 men from the radio school

the omission of Sundays and holidays. It is clear from this chart that for both groups the number of men reporting to sick call with respiratory complaints decreased definitely during the period of prophylaxis,

⁷ Thomson, Scott, and Glazebrook, A. J. Infectious Diseases in a Semiclosed Community, *J. Hyg.* 41: 570-615 (Dec.) 1941.

⁸ The Division of Laboratories and Research of the New York State Department of Health, Albany, cooperated in testing the toxigenic activities of these strains.

blood concentrations varied between 15 mg and 37 mg per hundred cubic centimeters with an average and median of 26 mg per hundred cubic centimeters.

Toxic reactions following the use of sulfanilamide in prophylactic doses in rheumatic subjects have been reported to vary from a few and mild by some workers to as high as 37 per cent in one report.⁹ In the present study, toxic reactions ascribable to sulfadiazine were very few. Only 3 men had rashes due to the drug, a fourth person who had previously suffered from urticaria developed an urticarial rash while taking sulfadiazine, this rash disappeared when the drug was discontinued but reappeared several days later in the absence of sulfadiazine. No gastrointestinal disturbances were reported by the men taking sulfadiazine and, while no systematic observations were made concerning blood changes or renal disturbances, no symptoms referable to such complications were reported.

COMMENT

This study indicates that sulfadiazine in doses of 1 Gm daily can effectively control an outbreak of scarlet fever. The conditions prevailing at the station were such that the entire personnel could be divided into two groups, one of which served as a control for the other during the period of prophylaxis.

⁹ Stowell, D. D., and Button, W. H., Jr. Observations on the Prophylactic Use of Sulfanilamide on Rheumatic Patients, with Report of One Death, *J. A. M. A.* 117: 2164-2166 (Dec. 20) 1941.

The results are even more striking when the epidemiologic situation is considered. About one fourth of the men remaining at the station for four months apparently acted as a focus from which a transient group, four times as large, was being infected. These conditions in certain respects resembled those which Webster¹⁰ and Greenwood and his associates¹¹ have shown to be most favorable for the perpetuation of epidemics among experimental animals and which Green¹² and Thomson and Glazebrook¹³ have described in British naval training schools, where they have studied epidemics of streptococcic respiratory infections.

There can be little question that sulfadiazine in small doses was effective in controlling the epidemic in both groups. The radio school personnel was started on treatment first, with a resulting sharp decrease in case rate, while simultaneously the incidence among the pier personnel remained high for the next three weeks. The pier group was then started on sulfadiazine, and both groups were continued on this drug for twelve days. This brought about a complete remission of scarlet fever in both which persisted until the end of the period of observation sixteen days after sulfadiazine was discontinued. These results accord with those reported by others concerning the efficacy of sulfanilamide in preventing streptococcic infections of the respiratory tract in rheumatic subjects.

The number of respiratory complaints at the daily sick call were also much reduced in both groups in the period during which sulfadiazine was given. This was not surprising, as many of these complaints were probably due to infections with group A hemolytic streptococci as well as to other sulfonamide susceptible micro-organisms.

The remission in scarlet fever, despite the persisting high carrier rate of type 19 streptococci, for at least sixteen days after withdrawal of the sulfadiazine was not expected. This may be explained in part by the intervening holidays, when many men were given leave, which probably caused a decrease in the number of both carriers and susceptible persons. On the other hand, it was not surprising to find a high carrier rate persisting after the use of the drug. Kuttner and Reyersbach¹ have shown that children receiving small doses of sulfanilamide may become carriers of group A hemolytic streptococci without showing any evidence of infection; we have found that even in full therapeutic doses sulfadiazine often fails to rid patients of these micro-organisms.

In the relatively small prophylactic doses used, sulfadiazine elicited a minimum of toxic symptoms, while extensive investigations of its effect on the bone marrow and kidneys of these subjects were not practical, no manifestations were encountered that would indicate any disturbance of these organs. It is now generally agreed that sulfadiazine is the least toxic member of the sulfonamide group. This report confirms that opinion, as the proportion of toxic reactions occurring in this study is less than that reported by any of the workers employing sulfanilamide prophylaxis in rheumatic children.

Besides the danger of immediate toxic reactions in employing sulfonamide compounds in prophylactic doses, one must bear in mind the possibility of producing drug fast strains as a future hazard and also the possibility of so sensitizing large groups of persons to the sulfonamide compounds that they might subsequently be unable to take these drugs for therapeutic reasons. The first possibility is largely speculative, the second has not been encountered in rheumatic subjects who have taken small doses of sulfanilamide over long periods.

The successful demonstration of chemoprophylaxis on a large scale to control an epidemic of scarlet fever raises the question as to when it should be employed. It probably should reinforce rather than replace other hygienic measures. The relative benefits, however, must be balanced against the disadvantages in considering any therapeutic measure. The disadvantages discussed would seem at present to be comparatively slight, especially when sulfadiazine is used. It must be recognized, moreover, that the minimum effective prophylactic dose has not yet been determined. The relative benefits will vary under different circumstances and hence must be judged in the light of all available data concerning the particular epidemiologic situation. The attitude might be assumed that all situations favorable to the development of streptococcic infections of the upper respiratory tract demand the immediate application of the most effective prophylaxis, because a certain number of such cases lead to rheumatic fever and nephritis. At the present time it does not seem practical to apply chemoprophylaxis on a large scale under endemic conditions in which a normal population is involved. The application of the modern techniques for grouping and typing streptococci are of considerable help in deciding whether or not conditions are favorable for the development of an epidemic. For example, at this station, through which men from all sections of the country were funneled rapidly, a certain number of cases due to many different types of streptococci were to be expected and would hardly constitute an indication for large scale chemoprophylaxis. When, in contrast, all cases were found to be due to a single type of strongly invasive capacity, the danger of rapid spread was great and the most effective prophylactic measures were indicated. If in addition the normal functions of an institution or community are seriously threatened by an epidemic, current arguments against such a method of control carry relatively little weight. Apparently the sulfonamide compounds in small doses, and especially sulfadiazine, offer very effective means for controlling streptococcic infections of the respiratory tract without disrupting essential military activities.

SUMMARY AND CONCLUSIONS

1. An epidemic of scarlet fever due to group A type 19 hemolytic streptococci occurred at a United States naval station.
2. Sulfadiazine in prophylactic doses of 1 Gm daily effectively controlled this epidemic and caused a pronounced reduction in the number of daily sick calls due to other respiratory complaints.
3. Among several thousand men treated only 3 had rashes due to sulfadiazine, and no major toxic reactions were observed.
4. Sufficient evidence has been obtained to justify the use of this drug in controlling epidemics of streptococcic infections of the respiratory tract.

CONGENITAL LARYNGEAL STRIDOR

LACK OF RELATION TO THYMIC DISEASES

ROBERT H. TRIMBY, M.D.

ANN ARBOR, MICH.

There exists a widespread tendency to place the blame for a respiratory abnormality of any magnitude in infancy on the thymus gland, particularly if there is x-ray evidence of thymic enlargement. In the absence of x-ray evidence it is often assumed, as pointed out by Wasson,¹ that the roentgenogram did not accurately portray the situation, and the thymus still may be believed to be the cause of the symptoms. It is not our purpose to review or to evaluate current opinion on thymic enlargement or so-called status thymicolymphaticus. We have been impressed, however, by the apparent confusion of congenital laryngeal stridor with thymic disease as indicated by the fact that in the past three years almost all infants in whom we have established the diagnosis of congenital laryngeal stridor had been referred to us with the diagnosis of enlarged thymus.

This paper thus has been prompted by an experience similar to that reported by Kennedy and New² and by Bowman and Jackson.³ The former authors reported a group of 30 cases of chronic stridor in childhood collected over a ten year period at the Mayo Clinic. Stridor was the chief complaint in only 15 of these cases, but 9 of these 15 had been diagnosed previously as thymic enlargement and in 8 of the 9 roentgen therapy had been given without benefit. Bowman and Jackson reported a similar group of 30 cases of stridor in all of which roentgenograms of the thymus had been made. Enlargement of the thymus was reported in 21 of these cases and in 19 roentgen therapy had been given. In 5 the symptoms seemed to be improved, another 5 showed temporary improvement and in 9 there was no change.

Congenital laryngeal stridor, the most frequently encountered form of chronic stridor in infancy, has been recognized as an entity for many years. Rilliet and Barthez⁴ in 1853 described a clinical picture resembling congenital laryngeal stridor, although credit is usually given to Lees,⁵ who in 1883 reported the examination of the larynx of a year old child. One month after being examined the child died of diphtheria. Both clinical and postmortem features were presented. Although congenital laryngeal stridor is not often encountered, it is worthy of attention, since, as pointed out by Thomson⁶ in 1892, it is apt to cause anxiety owing to its being mistaken for some more serious disease.

Thomson and Turner⁷ presented a classic description of congenital laryngeal stridor in 1900 when they stated that

The infant who appears normal in other respects is noticed shortly after birth to have noisy breathing. The noise consists of a croaking sound accompanying inspiration, which rises to a high pitched crow when a longer or more vigorous breath is taken, expiration may be accompanied by a short croak when the stridor is loud, but at other times it is noiseless. Even in the more severe cases there are brief intervals during which there is no sound audible, but with this exception the stridor goes on constantly while the child is awake and some times when he is asleep. Any emotional excitement or physical cause of deeper breathing, such as exposure to cold air or the exertion of sucking, is apt to intensify the sound. The child's power of crying is unaffected. The breathing, although noisy, is not accompanied by the slightest distress and there is no cyanosis. There is, however, marked inspiratory indrawing of the thoracic and abdominal walls except in the mildest cases. The stridor increases in loudness during the first few months and after remaining about the same for a few more months gradually lessens and disappears during the course of the second year. Long after it ceases to occur habitually, however, it is occasionally brought on again by emotional causes.

The larynx is fully developed at birth and increases in size to puberty, with no sex difference noted in infancy.⁸ The structures about the upper aperture are soft and readily collapsible. The epiglottis, cartilages of Wrisberg and apexes of the arytenoid cartilages are composed of yielding, elastic cartilage. The rest of the larynx is of brittle hyaline cartilage. Calcification due to the deposits of lime salts takes place much earlier in hyaline than in the yellow elastic or white fibro cartilage. While perhaps not of importance in the infant's larynx, these factors do point to a fundamental difference in consistency.

Thomson and Turner⁷ give an excellent description of the abnormality responsible for congenital laryngeal stridor and from experiments conducted with the larynxes of stillborn infants showed that three component changes occurred: (1) The sides of the larynx were sucked together so as to form a narrow mesial slit, (2) the epiglottis was drawn backward and downward so as to form a slit, (3) the arytenoid cartilages met in the midline while the margins of the anterior portion of the aperture remained unaffected. Although they stated that the change found in congenital laryngeal stridor was merely an exaggeration of the normal infantile type of larynx, they felt that the primary element of etiology was a disturbance of respiratory movements due to some backwardness of cortical control and that the recurring sucking in of the upper aperture of the soft larynx was induced by the ill coordinated and spasmodic nature of the breathing. No other writer has agreed with this opinion, and not one of our cases has shown lack of cortical control.

Sutherland and Lack⁹ in 1897 presented 18 cases of stridor in which 6 had been examined with a laryngeal mirror. They described the epiglottis as rolling back on itself, the arytenoepiglottic folds being approximated and flaccid, flopping to and fro on respiration and the laryngeal aperture being reduced to a mere slit. With

the advent of direct laryngoscopy, the pathologic physiology was directly observed. McKenzie¹⁰ reported direct laryngoscopic observations made by D. R. Paterson in which the latter saw "with each inspiration the soft parts of the cricoid, including the arytenoids and interarytenoid folds disappear so to speak into the interior of the larynx, being drawn downward and forward and to such an extent in pronounced cases that the upper border of the cricoid could be seen as a transverse ridge through the stretched mucous membrane." The sides of the orifice were also observed to be sucked in, and when he held one side up with forceps the noise stopped at once.

Hill⁵ in 1930 stated that since the structures were of a different histologic structure, predisposing to flaccidity, and were of a different embryologic origin, highly specialized they might be subject to sufficient variation it not malformation to produce the condition of congenital laryngeal stridor. In other words, the situation was thought to be an exaggeration of the infantile type of larynx, differing from normal only in degree, and that the stridor was probably due to the vibrations of the flabby epiglottis and unsupported arytenoepiglottic folds being sucked inward on inspiration. The pathogenesis described by the latter authors seems fulfilled in our cases.

REPORT OF CASES

Case 1 which was under observation for three years, exemplifies the confusion of this condition with thymic enlargement. It also illustrates the frequency with which infections of the upper respiratory tract occur in these patients.

CASE 1—J. O. aged 1 month was seen because of choking and dyspnea which had been present since the age of 5 days. X-ray examinations of the chest purported to show an enlarged thymus; he was given two courses of roentgen therapy within six weeks without relief from symptoms and a full supracardiac X-ray shadow persisted. Transmitted throat sounds were audible on auscultation of the chest and there was striking retraction of the lower portion of the sternum on inspiration. At the age of 4 months he was subjected to direct laryngoscopy at which time it was noted that a redundant mucous membrane over the left arytenoid cartilage dropped over the glottis on inspiration. The vocal cords were normal. Since the symptoms persisted laryngoscopy was repeated one month later. The same picture was noted and in addition there was some backward curling of the epiglottis with inspiration. The symptoms persisted in varying degree intensified by infections of the upper respiratory tract and at the age of 16 months laryngoscopy was again done. The flaccid state of the arytenoids persisted with rotation over the posterior portion of the glottis with each inspiration. The epiglottis was likewise still flaccid. The patient did not return again until the age of 3 years 9 months at which time he had a chronic infection of the upper respiratory tract but no stridor. Direct examination of the larynx still showed the arytenoids to be covered with an excessive mucous membrane. When seen at the age of 3 years he had a mild pharyngitis but was otherwise well apparently having completely outgrown the stridor.

CASE 2—M. M. was noted at birth to have noisy respiration and a slight cough. At the age of 3 weeks a pulmonary infection developed from which he recovered without incident but reexamination at the age of 7 weeks showed a slight cough, noisy respiration and with each inspiration retraction of the suprasternal notch and of the lower portion of the sternum. He was seen again at the age of 6 months at which time the

stridor seemed to be improving but was still quite pronounced when the patient was placed flat on his back or when he cried vigorously. Direct laryngoscopy at this time showed a tiny soft epiglottis which had a tendency to fold over the glottis on inspiration. The vocal cords moved normally.

CASE 3—W. B. was seen at the age of 7 weeks with a history of persistent crowing respiration first noted on the second day of life. At that time he had been placed in an oxygen tent because of slight cyanosis and since an X-ray examination of the chest showed a supposedly enlarged thymus he received two X-ray treatments, but without benefit. The stridor had persisted and he had not taken his feedings well. When examined at the age of 7 weeks a loud crowing sound accompanied by retraction of both the suprasternal notch and the lower sternum was noted with each inspiration. He was moderately undernourished but hyperactive. Direct laryngoscopy revealed a small epiglottis which was occasionally drawn downward and collapsed during inspiration. During three weeks of observation there was no essential change in his condition.

CASE 4—E. H. had had noisy and difficult breathing since birth. The noise, heard during inspiration, was most pronounced when she was flat on her back. She also had some difficulty in taking feedings. The infant had received two X-ray treatments for questionable thymic enlargement, one at 1 week and the other at 4 weeks, both without benefit. When she was examined at 2 months a loud inspiratory wheeze or stridor was noted along with retraction of the lower portion of the sternum. These symptoms were somewhat relieved by protruding or extending the chin. The jaw was questionably shortened. Direct laryngoscopy revealed a limber epiglottis which on inspiration folded together and was drawn into the glottis, causing definite obstruction.

CASE 5—R. S. had had difficulty with respiration since birth and had had three X-ray treatments within the first ten days of life since a roentgenogram of the chest had been interpreted to show an enlarged thymus. However the stridor persisted and gradually became worse. When seen at the age of 2 months a well defined inspiratory stridor was noted which was considerably relieved by placing the patient face downward. Definite retraction of the sternum accompanied each inspiration. Direct laryngoscopy revealed a small short curled epiglottis which was retracted toward the larynx with each inspiration. When the epiglottis was engaged with the laryngoscope the vocal cords were seen to have a normal range of motion with no abnormality. When the epiglottis was held toward the crowing and stridor ceased.

CASE 6—S. B. was sent to the hospital at the age of 4 months with a diagnosis of enlarged thymus. She had had a low pitched inspiratory wheeze since the age of 3 weeks. Direct laryngoscopy at 4 months revealed an excessively flexible epiglottis with medial contraction of the arytenoids on inspiration. Both vocal cords were visualized and noted to have normal structure and function.

CASE 7—M. W. was noted to have a stridor at the age of 10 days. This had persisted and the patient presented a mild feeding problem. X-ray examinations of the chest at the age of 6 weeks were negative for enlargement of the thymus. When seen at the University Hospital at the age of 3 months inspiratory stridor was present and laryngoscopy revealed that the right arytenoid was collapsed anteriorly and with each inspiration the left arytenoid would also be pulled anteriorly. Vocal cords and epiglottis were normal.

CASE 8—R. D. began at the age of 10 days to have stridor and difficulty in respiration. When seen at the age of 1 month the crowing inspiratory sounds were obvious. There was no retraction of the sternum but a suggestive slight cyanosis was noted. Direct laryngoscopy revealed no significant evidence of acute infection. The epiglottis was normal in curvature but lacked sufficient cartilaginous support, so that with each inspiration it was retracted into the vestibule.

10 McKenzie, D. Congenital Laryngeal Stridor with Dysphagia. *J. Laryng. & Otol.* 40: 255 (May) 1925.

CASE 9—W was noted to have a suggestive obstruction to respiration during the first three days of life. This subsided somewhat, but she had some difficulty in eating. At the age of 1 week direct laryngoscopy revealed that the epiglottis was slightly increased in size and had a minimal horseshoe appearance. During normal respiration no signs of abnormality were present but when the child cried there was a moderate inspiratory sudden swing of the epiglottis over the glottic chink. The larynx was otherwise normal.

CASE 10—W C, aged 2 months, had had episodes of difficult breathing and a peculiar grunt since birth. This had frequently been noted just after the child had gone to sleep. The difficulty seemed to be inspiratory with a slight retraction of the lower part of the sternum and occasionally an expiratory rattle. A noisy gurgling respiration was noted but there was no difference between inspiration and expiration or any retraction. The laryngologist thought the epiglottis was shorter than normal but he could see no abnormal flaccidity. Although this case is not clear, the symptoms were largely those of laryngeal stridor and were attributed to moderate relaxation of the supraglottic structures.

CASES IN WHICH LARYNGOSCOPY WAS NOT DONE

CASE 11—J U had a crowing inspiratory sound first noticed at the age of 2 weeks. He had had several minor choking spells, but during his fifth week three severe episodes of choking occurred. He was then referred with a diagnosis of laryngismus stridulus. Physical examination revealed the stridor and a questionable short mandible. It was thought that the choking spells were due to eating too fast. X-ray examinations of the chest showed questionable moderate enlargement of the thymus but no significant degree of tracheal compression.

CASE 12—W L was seen at the age of 7 weeks chiefly because of a lumbar meningocle with associated paralysis of legs and loss of sphincter control but in addition he had so had wheezing respiratory sounds, noticed since the mother had first seen him at the age of 10 days. This wheeze was not noticed at night or when he was placed on his stomach. Examination revealed the typical inspiratory sounds of congenital laryngeal stridor.

COMMENT

In the study of a patient with chronic stridor a careful history and complete physical examination are essential. Study for thymic disease may be made by fluoroscopy and by films of the chest and neck according to the method of Pancoast and Pendergass.¹¹ It might be considered axiomatic that any stridor in infancy should be investigated by direct laryngoscopy.⁹ According to Tucker¹² the indications for direct investigation of the infant larynx are (1) symptoms of difficulty in phonation, including aphonia and croupy cough, and (2) symptoms of difficulty in breathing, including stridor, dyspnea and wheezing, with evidence of laryngeal obstruction as manifested by indrawing of the suprasternal notch and the tip of the sternum.

Although congenital laryngeal stridor is the most common cause of stridor in early infancy, other conditions may be encountered. However, no attempt will be made to discuss in detail these various conditions, which must be considered in the differential diagnosis of chronic stridor in infancy.¹³ Various congenital anomalies, such as a small glottic lumen, congenital web

below the glottis and papillomas have been observed, while congenital malformation of the heart associated with rapid respiration and cyanosis has been mistaken for thymic disease. Micrognathia or macroglossia may cause obstruction. Spasm of the laryngeal muscles in tetany may be sufficient to cause noisy respiration. It may be emphasized that simple enlargement of the thymus is rarely a cause of respiratory difficulty. Thymoma or other mediastinal tumor, hypertrophic laryngitis and tuberculous bronchial nodes may produce such symptoms. Adenoid hypertrophy may produce a snoring respiratory sound and persistent cough due to the nasopharyngeal secretion entering the larynx. Perilaryngeal disease, such as retropharyngeal abscess, peritonsillar abscess and cervical abscess may easily produce stridor. A foreign body should always be considered especially with the history of an explosive type of cough, while diphtheria and laryngotracheobronchitis may have to be considered in older infants showing signs of acute infection.

Since the symptoms of congenital laryngeal stridor usually disappear spontaneously during the second year, no active treatment is necessary. However, the infant is usually more comfortable and less bothered by respiratory embarrassment if kept on the side or on the face. Patients with congenital laryngeal stridor seem unusually susceptible to respiratory infections and require special care during them. In severe cases tracheotomy may be required. Since infants with congenital laryngeal stridor have some dysphagia, the volume of the formula offered should probably be reduced as much as possible. Iglaue¹⁴ has reported a case in which epiglottidectomy was done with relief from symptoms.

SUMMARY

Congenital laryngeal stridor, the most common form of stridor in infancy, must be differentiated from other congenital abnormalities which interfere with respiration, such as a small glottic lumen, congenital web below the glottis, micrognathia, macroglossia, laryngeal papilloma and cysts. Laryngeal spasm, perilaryngeal abscess, mediastinal tumor, foreign body and at times acute infections are important considerations. However, congenital laryngeal stridor has been most frequently confused with thymic disease, but simple thymic enlargement is rarely responsible for respiratory embarrassment in infancy. The pathology in congenital laryngeal stridor lies in an exaggeration of the infantile type of larynx with undue relaxation of the supraglottic structures. An accurate diagnosis can be made by direct laryngoscopy. The roentgen ray is a valuable aid in the study of these patients but roentgen therapy is without avail. Since this condition is usually outgrown, active therapy is seldom required.

¹³ The classification of conditions that need to be considered is reported by Neffson, A. H., and Wishik, S. M. Acute Infectious Croup. *J. Pediat.* 5: 633 (Oct.), 617 (Nov.), 776 (Dec.) 1934.

Podagra—Gout, gicht (German), gota (Spanish), goutte (French) and gotta (Italian), respectively, have been adapted from the Latin etymon gutta, which implies a drop or exudation.

Gout was known to the ancients as *podagra*, a Greek derivation from *pous*, foot, and *agra*, attack. The condition is not surprising since gouty arthritis appears first in the feet in the majority of afflicted persons.—Talbot. *John H. Gout*, New York, Oxford University Press, 1943.

Clinical Notes, Suggestions and New Instruments

THE TREATMENT OF EPIDEMIC KERATOCONJUNCTIVITIS WITH SODIUM SULFATHIAZOLE DESOXYEPHEDRINE

H S CRADLE MD CHICAGO AND C H HARRISON MD
WALKEGAN ILL

In the stress of these war times every man hour is of the hour of victory. The first cause is beyond medical control, but we can do something about the second. Epidemic keratoconjunctivitis has taken an enormous toll of man-hours during the past year for the average loss of working time incurred in each case is from fourteen to eighteen days. Consequently any measure that can reduce such wastage is worth trying, even though it may not be uniformly successful. On that basis we are reporting the use of a new therapeutic measure that in our hands has proved worth while. It is realized that the number of cases is small that the results are only those of clinical observation and that the accurate serologic proof is missing.

Two years ago Turnbull of Los Angeles developed a stabilized solution of sodium sulfathiazole and a vasoconstrictor for the treatment of upper respiratory infections; this solution was later modified for use in ophthalmology. Our interest in the application of the ophthalmic solution in the treatment of epidemic keratoconjunctivitis was a result of a personal communication with Dr George R Hazel of the Department of Clinical Research, Abbott Laboratories who supplied the preparation to us. The solution contains 1 per cent sodium sulfathiazole stabilized by 0.5 per cent of sodium sulfite to which has been added 0.1 per cent of desoxyephedrine. It is stable nonirritating and buffered to a pH of 9.0. The toxicity is low, the lethal dose for mice being approximately 100 mg per kilogram of body weight. In ophthalmic practice the solution is used as eye drops. It has been administered by H S Gradle as two drops in each eye three to five times in twenty-four hours, by G H Harrison as one drop in the affected eye every waking hour. In all cases the treatment was continued for a reasonable period of several weeks after the acute phase had subsided. It produces a mild smarting sensation that disappears within a minute or two.

The cases were observed in four distinct and separate series:

- 1 Those seen in private practice by Dr H S Gradle
- 2 Those seen at the Illinois Eye and Ear Infirmary by Dr H S Gradle and members of the staff
- 3 Those seen in industrial practice by Dr G H Harrison
- 4 Those seen in private practice by Dr G H Harrison

The total number was an even 50 of which 43 have been followed upward of four weeks. As diagnostic criteria the following findings were considered:

- 1 Acute conjunctivitis with conjunctival and periorbital edema and/or pseudomembranes and/or occasional petechial hemorrhages of the conjunctival surface
- 2 Preauricular or submaxillary glandular swelling and/or tenderness
- 3 Presence of monocytes in conjunctival scrapings and absence of causative pyogenic organisms
- 4 Characteristic corneal involvement
- 5 Little or no conjunctival secretion and that of a purely serous type

At least three of the aforementioned factors were considered necessary for a positive diagnosis. The advance or recession of the pathologic process during the course of treatment was based purely on clinical observation. Unless specific indications were present no other medication was used except sodium sulfathiazole desoxyephedrine.

We have the definite impression that there are three clinical phases to epidemic keratoconjunctivitis. The first is the stage

of active conjunctivitis with concurrent symptoms. In the second stage there are no conjunctival subjective symptoms but the conjunctiva is still injected and highly edematous and during this stage the corneal infiltrates are most apt to appear. In the third stage the conjunctiva is pale but the corneal involvement persists. Stages 1 and 2 merge into each other without any sharp dividing line. It is probable that during stage 2 infectivity disappears but that is now the subject of investigation with controls by G H Harrison. It is our definite clinical impression that under the use of sodium sulfathiazole desoxyephedrine the time of stage 1, which untreated runs from fourteen to eighteen days is reduced to three to seven days. With other forms of treatment in our experience stage 1 runs its full course. Owing to the lack of controls we are not able to say whether stage 2 and stage 3 are materially influenced by the solution although we have the impression that corneal infiltrates are fewer and thinner than in cases treated by other methods.

CONCLUSIONS

In sodium sulfathiazole desoxyephedrine we have a new medication that is harmless to the ocular tissues. It appears to be of great value in epidemic keratoconjunctivitis and reduces the time of the acute conjunctival aspect to three to seven days. It does not seem to prevent the appearance of corneal infiltrates but we have the impression that when infiltrates do appear they are less numerous and less severe than in untreated cases. The subjective discomforts of epidemic keratoconjunctivitis disappear under this treatment with amazing rapidity.

55 East Washington Street

FAMILIAL SYRINGOMYELIA

COLONEL CHARLES R MUELLER
MEDICAL CORPS ARMY OF THE UNITED STATES AND
MAJOR SAMUEL J SUGAR
MEDICAL CORPS ARMY OF THE UNITED STATES

Recently we had an opportunity to study four brothers in a family each disabled by a disorder of the lower extremities characterized by (1) exaggerated callus under the great toe, insidious in appearance (2) progressive ulceration at the site of the callus eventuating in amputation at various levels and (3) anesthesia of varying extent in the part involved.

The condition reported herewith is variously known as familial neurotrophic osseous atrophy,¹ status dysraphicus-mielodysplasia² and syringomyelia.³ No definite causative agent has been disclosed. In the cases under discussion the familial background is striking. Four male siblings and three male relatives have similar if not the same disease.

FAMILY HISTORY

All the members of the family investigated were born in Scotland. The father of the four men who now have the disease died at the age of 52 of paralysis following sleeping sickness. He is not known to have had any disorder of the feet. The mother at 51 is living and well. Her brother and one nephew had amputations of the leg because of gangrene of the foot. Another nephew was discharged from the British army because of chronic ulcer of the right great toe. A daughter is living and well without symptoms of disease of the extremities.

The brothers described here were all of fair complexion with light brown hair, brown eyes and of medium stature ranging in height from 5 feet 4 inches to 5 feet 8 inches.

From the Medical Service, Lovell General Hospital, Fort Devens, Massachusetts.

REPORT OF CASES

CASE 1—J. M., a man aged 28, was inducted into the U S Army in February 1941. After a long hike the soldier sought medical care because of a blister under the right great toe. He had noticed a hard callus on the plantar surface of this toe for more than four years. At infrequent intervals the callus

would become ulcerated and drain. There was no associated pain, and the ulcer would heal slowly and spontaneously. With local moist heat and rest, the condition improved so that the patient was able to return to duty. However, the blister soon reappeared, became infected and refused to heal completely, so that prolonged hospitalization became necessary.

There was no history of migratory phlebitis or intermittent claudication. The general physical examination except for the foot was essentially negative or within normal limits. Both feet were cool and moist. There was no abnormal pitting on elevating or redness on lowering the feet. The pulsations of the dorsalis pedis and posterior tibial arteries were

easily palpable and of good volume. On the plantar surface of the right great toe near the medial border a small crater shaped ulcer 1 by 2 cm in diameter could be seen (fig 1). This was a dark purple and was surrounded by heavy callus. Roentgenograms of both feet did not reveal any abnormality of the bone. Neurologic examination revealed equal and active achilles and patellar reflexes. Vibration and position sense were intact. There was a definite sensory dissociation confined only to the toes of both feet, light touch was present but pain and temperature sensibility were absent. Circulatory function tests with the oscillometer and intracutaneous histamine revealed normal circulation and good capillary response. Repeated blood counts, urinalyses, spinal fluid examinations, blood chemistry analyses and Kahn tests all gave negative results or results within normal limits. Roentgenograms of the skull, chest, entire spine and feet were negative. A tuberculin test with 1:10,000 dilution was positive.

His course in the hospital was marked by an extension of the area of sensory dissociation to include both legs as far as the knees. The ulcer stubbornly refused to heal, the callus surrounding it gradually increased in size and the patient was discharged from the U S Army because of physical disability.

CASE 2—G. M., the eldest brother, at the age of 21 noticed a hard callus under the right great toe. This became ulcerated, drained and refused to heal. The toe became swollen, discolored and gangrenous, so that amputation became necessary. This was followed by gangrene of the second right toe, which brought about the amputation of that digit. A few years later the patient accidentally stepped on a nail. Chronic osteomyelitis of the right foot developed and amputation of the anterior portion of the right foot was performed. A slough developed on the lateral portion of the amputation stump. This stubbornly refused to heal and recently amputation of the remaining portion of the right foot became necessary.

CASE 3—A. M., the youngest brother, at the age of 19 complained of a painful corn on the right little toe. This became swollen, but roentgenograms showed no destruction of the bone. A draining sinus developed in this toe and a segment of bone discharged spontaneously. The sinus then healed, leaving a flail toe. Subsequent roentgenograms revealed that only a small portion of the proximal phalanx remained (fig 2). Meanwhile, a callus had developed on the plantar surface of the right great toe. Occasionally a blister would form in this callus but no ulceration followed. Examination revealed sensory dissociation involving only the right little toe. Dorsalis pedis and posterior tibial arteries were normal. Vibration and position sense were intact. He was inducted into the Army and in a few months had to be hospitalized because of a persistent ulcer of the right great toe.

CASE 4—V. M., the fourth brother, at the age of 16 had a slight injury to the left leg when he vaulted a 5 foot fence. The ankle became swollen but not painful and refused to subside over a period of six months. He was studied thoroughly at a hospital in Boston. "There was diminished sensation of the peroneal nerves of left and right" and the condition was diagnosed as syringomyelia. The ankle grew larger without pain, complete and detailed studies failed to reveal a definite causative agent and amputation below the left knee finally became necessary. Following a fall on the stump, an ulcer formed which was very sluggish in healing but eventually disappeared, so that the patient was able to walk with an artificial limb. At this time blood serologic tests, spinal fluid and neurologic examinations of the mother were all negative.

COMMENT

The clinical picture of intractable callus forming under the large toe, tending to erode and ulcerate and to be associated with progressive anesthesia of the affected extremity, is uncommon. When known to affect other male members of the family

tree the diagnosis of syringomyelia or one of its synonyms is always more than likely. The only diseases to be differentiated are syphilis, tuberculosis, osteomyelitis and leprosy. The first three are ruled out on clinical and laboratory evidence. One of us (C. R. M.), who has had clinical experience with leprosy, felt that these cases did not fall into this category.

CONCLUSIONS

1. Four members of a family group present a common disability characterized by callus formation with subsequent ulceration and anesthesia of the great toe.

2. The demonstration of sensory dissociation in three brothers points to syringomyelia as the most likely diagnosis.

3. The disease is further characterized by a tendency to occur only in the males and by a chronic progressive course resisting all forms of treatment.

HOWARD A. CARTER, Secretary

MODEL J GALVANIC GENERATOR ACCEPTABLE

Manufacturer: H. G. Fischer & Co., 2325-2345 Wabasha Avenue, Chicago

The Model J Galvanic Generator is designed primarily for muscle stimulation. It generates five current forms designated by the firm as (1) straight galvanic, (2) galvanic surge, (3) slow sinusoidal, (4) rapid alternating 240 cycle per second and (5) rapid alternating in surges. Four of the currents are for muscle stimulation. Current 2 galvanic surge and current 3 slow sinusoidal are designed for muscles deprived of their nerve supply. Currents 4 and 5 are to be used for stimulation of a muscle with nerve supply intact. Current 1 is employed for ion transfer and the usual direct current applications.

Experiments were made on the denervated and normal tibialis anterior muscles of dogs and monkeys. In addition these currents were tested on several patients in the physical therapy clinic of a medical institution as well as on a group of normal subjects. The tests undertaken showed that:

CURRENT 1—Straight galvanic can be used for any therapeutic procedure requiring a source of direct current. It is suggested that the current be designated direct current.

Fischer Model J
Galvanic Generator

CURRENT 2—This galvanic surge current will produce muscle contractions of the denervated muscle. Contractions secured with this current are either anodal closing contractions or cathodal closing contractions. The current does not alternate from positive to negative with each electrical cycle. Each surge has the same polarity. Some clinicians might favor this type of current for a paralyzed muscle showing a polar reversal. It might also be used where the polar reactions of the direct current are desirable in addition to the muscular contractions. It is suggested that this current be designated 'surging uninterrupted direct current with constant polarity.'

CURRENT 3—This slow sinusoidal current was found to provide adequate muscular contractions of denervated muscles. It is the best of the five currents for the stimulation of the paralyzed muscle. The current form was not checked to determine whether it conformed strictly to the sine law, and in view of former studies it probably does not. However, there is no evidence that it should do so. It is suggested that this current be designated a 'surging uninterrupted direct current with alternate polarity.'

CURRENT 4—This rapid alternating 240 cycles per second current causes a completely fused and sustained tetanus of the skeletal muscle with an intact nerve supply. It can be used for those therapeutic procedures requiring the so called 'tardic stimulation.' It is suggested that this current be designated a 'tetanizing current.'

CURRENT 5—This current rapid alternating in surges, was found to be effective in stimulating the skeletal muscle with an intact nerve supply. All five currents can be utilized as outlined. Three of the five currents on this generator can be classified as absolutely essential, namely Nos. 1, 3, and 5. Current 2 might be considered essential by some clinicians; however, there is no evidence available that such is the case. The Council considers it justifiable to include such a current on theoretical considerations and in deference to those clinicians who might desire to use such a current. Current 4 might well be included although it is not an essential current.

While these currents are effective as outlined, they are not to be considered as ideal by any means. Until ideal currents are developed, this generator should serve a useful purpose.

The Council voted to accept the Model J Galvanic Generator for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT
ALSTIN E. SMITH, M.D., Secretary

DIETHYLSTILBESTROL

The Council first accepted preparations of diethylstilbestrol in 1942 with the stipulation that in view of the data on toxicity, the acceptance be limited to one year at which time the question would be reconsidered (THE JOURNAL, June 20, 1942, p. 632). The period having elapsed, the Council reconsidered this matter. It was reported that the literature for the past year contained no report on diethylstilbestrol which would affect the continued acceptance of diethylstilbestrol. The drug's toxicity has not become any more apparent, the clinical assurance which comes from more prolonged use increases confidence in the material, and its efficacy is about what it was judged to be when the first preparations were accepted.

The Council voted therefore to extend the period of acceptance of brands of diethylstilbestrol to the end of 1945 (the regular three year period of acceptance) unless in the meantime information becomes available which would necessitate reconsideration of this decision.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ALSTIN E. SMITH, M.D., Secretary

DIETHYLSTILBESTROL (See Supplement to New and Nonofficial Remedies 1942, p. 26)

The following dosage forms have been accepted:

ELI LILLY & COMPANY, INDIANAPOLIS

Ampoules Diethylstilbestrol (in cottonseed oil) 0.5 mg per cc 1 cc

Ampoules Diethylstilbestrol (in cottonseed oil) 1 mg per cc 1 cc

Ampoules Diethylstilbestrol (in cottonseed oil) 5 mg per cc 1 cc

Suppositories Diethylstilbestrol 0.5 mg and 1 mg

Tablets Diethylstilbestrol 0.1 mg, 0.25 mg, 0.5 mg, 1 mg and 5 mg

POISON OAK EXTRACT (See New and Nonofficial Remedies 1942, p. 21)

The following dosage form has been accepted:

PITMAN-MOORE COMPANY, INDIANAPOLIS

Poison Oak Extract with Sterile Diluent 1 cc vial marketed in a package also containing three 0.9 cc vials of sterile diluent consisting of a sterile isotonic salt solution containing procaine hydrochloride 0.5 per cent and chlorobutanol 0.4 per cent.

Fresh leaves of *Rhus diversiloba* dried at temperatures not exceeding 60°C and sieved to remove stems and leaf midribs are macerated with absolute ethyl alcohol using 20 cc of alcohol for each gram of dried leaves. The extract is filtered through paper, then diluted to five times its original volume by adding absolute ethyl alcohol.

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies 1942, p. 562)

The following dosage forms have been accepted:

THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO

Tablets Nicotinamide 50 mg

Sterile Solution Nicotinamide 50 mg per cc 15 cc vials Chlorobutanol 0.5 per cent added as a preservative

NICOTINIC ACID (See New and Nonofficial Remedies 1942, p. 561)

The following dosage form has been accepted:

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampule Solution Nicotinic Acid 1% W/V, 10 mg per cc 10 cc

CATARRHAL AND HUMAN SERUM
JAUNDICE

The etiology of the disease or diseases commonly called catarrhal jaundice, infective jaundice or infective hepatitis is not at all well understood. While frequently epidemic, it is not clear how it is spread. There is no evidence that water, milk, food or rodents serve as spreaders. The facts at hand point to droplet infection and close personal contact as the means of spreading. As yet a definite etiologic agent has not been found. This is true also in the case of the jaundice that may follow the injection of human blood, plasma or serum, either when used alone, as in transfusion and in treatment with convalescent serum or as until recently in certain yellow fever vaccines.¹ All the forms of human serum jaundice so far recognized are discussed in full detail in a recent special memorandum by medical officers of the British Ministry of Health.² It appears highly probable that further cases of human serum jaundice are bound to occur from the use of pooled convalescent human serum, especially measles as well as mumps and other forms, and especially after transfusion.³ How human blood products may acquire transmissible icterogenic properties clearly requires investigation. As yet it has not been determined whether there was a history of jaundice in any donor to pooled plasma or serum that caused jaundice.

Findlay and Martin⁴ have produced jaundice in 3 human volunteers by instilling into the nares nasal washings in salt solution from as many patients in the preicteric or early icteric stages of jaundice following injections of yellow fever vaccines. In the 3 vol-

unteers the symptoms, which were altogether like those of spontaneous infectious jaundice, came on after twenty-eight, thirty and fifty days. The volunteers had been immunized eight months previously with a yellow fever vaccine that did not cause jaundice. It seems safe to say without going into details that fault cannot be found with the way this experiment was carried out and that the attacks of jaundice in the volunteers were not due to chance infection but to the introduction of an infective icterogenic agent from the nasopharynx of patients with mild forms of jaundice following yellow fever immunization. Findlay and Martin mention that Voegt⁵ produced infectious jaundice in human volunteers by the oral administration of duodenal washings and by the subcutaneous and intramuscular injections of serum and blood from patients with the disease. Thus far suitable experiments with human material in a variety of animals have failed to produce infectious jaundice. Whether the infectious agency brought to light by the experiments of Voegt and of Findlay and Martin is responsible for the jaundice in yellow fever inoculation and similar conditions, as well as of the ordinary catarrhal jaundice, will have to be determined, if possible, by future research. The experiments do indicate the presence in the donors of the materials inoculated of an icterogenic agent or agents, perhaps of virus nature.

The length of time between the injection of icterogenic yellow fever vaccine and the appearance of the jaundice, namely from sixty to one hundred days or longer, has been cited as evidence that this form of jaundice is different from catarrhal jaundice, in which the incubation period is usually stated to be much shorter. It is rather doubtful whether the true incubation periods in these cases have been determined exactly enough to be reliable. In catarrhal jaundice it is extremely difficult to fix the date on which infection occurs. In both forms of jaundice the incubation period appears to be subject to wide variation. In the cases of jaundice following convalescent serum and transfusion of human blood or plasma the incubation has been prolonged up to one hundred days and more. The apparent absence of secondary cases in postinoculation jaundice has been advanced as another reason for regarding the two forms of jaundice as different. But it appears that secondary cases may occur. Findlay and Martin refer to an instance of probable transmission of infectious jaundice from inoculated British war personnel to uninoculated African war personnel. Then there is the instance described by Probert⁶ and two

children came down with jaundice two months after they had been in close contact with 7 children in whom jaundice developed after the injection of convalescent measles serum. From the foregoing it is clear that there must be, in addition to attempts to solve the problems of the etiologic relationship between viral and homologous serum jaundice, attempts to explain how human blood plasma or serum may acquire transmissible icterogenic properties in order that human blood products may be made safer for therapeutic use.

INTRAVENOUS ALIMENTATION WITH AMINO ACIDS

Among the important problems in the reduction of postoperative mortality after major surgical procedures is the persisting high incidence of pulmonary complications. Walters and his associates demonstrated that pulmonary complications occur with greater frequency in elderly malnourished patients than in others. At the University Hospitals of Cleveland, according to Studley, the mortality rate associated with gastric resection paralleled closely the magnitude of the loss of weight in patients with chronic peptic ulcer. Abbott and Mellors¹ now note that patients with moderate anemia on admission to the hospital, when given 1,000 to 2,000 cc. of whole blood prior to operation often did much better than patients who had normal blood values on admission and who did not receive transfusions. Apparently, a decrease in the plasma volume associated with chronic dehydration can mask anemia and hypoproteinemia.

An unselected group of 14 patients with carcinoma of the gastrointestinal tract or pyloric stenosis due to ulcer were studied. The authors demonstrated that severe dehydration may exist in patients who have shown a moderate loss of weight and a diminished intake of food and fluid even though vomiting has not occurred or has been minimal. Normal hematocrit values, red blood cell contents, hemoconcentrations and plasma protein concentrations may be obtained when dehydration is accompanied by malnutrition. Patients who have diminished total circulating plasma proteins are likely to have in addition, a deficit in tissue proteins in the liver and other organs. This is in keeping with the fact that a negative nitrogen balance exists. The authors therefore emphasize that any replacement therapy should aim at restoring the entire protein deficit of the body and of supplying adequate calories so that the body will not need to derive energy from the breakdown of its own tissues.

Whipple, Hartzell, Winfield and Ervin have called attention to the role of hypoproteinemia in patients with wound disruption. Ravdin and his associates noted wound disruption in 70 per cent of dogs operated on in the presence of hypoproteinemia. Ravdin stressed that attempts to restore a normal fluid and electrolyte balance in the presence of hypoproteinemia, without at the same time increasing the colloid osmotic pressure by adding to the plasma, too frequently result only in adding to the extravascular fluid reservoirs. The amino acids are the structural units of tissue proteins, their availability therefore is of primary importance. It would appear more logical to associate wound disruption with the presence and the extent of negative nitrogen balance rather than solely with the concentration of plasma protein. Thus the wound of the patient on whom cholecystogastrostomy was performed for carcinoma of the head of the pancreas disrupted when the concentration of protein was above 6 Gm. per hundred cubic centimeters and the catabolic process was probably at its maximum. Later, severe persistent decubitus ulcers and the severe lesion of the mouth healed rapidly when the plasma protein concentration was around 5 Gm. per hundred cubic centimeters and the body was receiving adequate calories and protein so that a relatively normal anabolic process existed. This rapid healing has also been noted in treating similar patients with repeated transfusions of plasma.

Patients with malnutrition require from 50 to 80 Gm. of nutritionally adequate protein daily and sufficient total calories to protect this. This can be accomplished by parenteral administration of dextrose in adequate amounts so that proteins will not be metabolized solely for body energy but rather be spared so that the constituted amino acids may enter into the synthesis of other tissue proteins. Since it is not practical to administer 1,000 cc. of plasma daily (containing approximately 70 Gm. of protein) a preparation containing amino acids more or less in the proportion in which they occur in a biologically complete protein would seem to be a likely substitute. Such a product has been employed at the University Hospitals of Cleveland without any apparent ill effects. Patients have been maintained in positive nitrogen balance when their sole source of nitrogen has been 15 per cent amino acids given intravenously. The only difficulty experienced was associated with administration of adequate amounts of dextrose. Thrombosis of veins frequently occurs after twenty-four to seventy-two hours of administration of 10 per cent dextrose. This difficulty can be avoided by the employment of the Tocantins method of intrasternal injection. Oral feedings or the method of

¹ Abbott W. E. and Mellors R. C. Total Circulating Plasma Proteins in Surgical Patients with Dehydration and Malnutrition. Indications for Intravenous Alimentation with Amino Acids. Arch. Surg. 46: 277 (Feb.) 1945.

oral-jejunal tube feedings advocated by Stengel and Ravdin would be the most physiologic and desirable methods when possible.

Estimations of plasma chloride concentrations are likely to give one a false sense of security. A low plasma chloride level determination does not per se give one an idea as to how much isotonic solution of sodium chloride can be administered safely. The only reliable index of the amount which could be tolerated safely is that of the total circulating plasma proteins. The total circulating plasma proteins frequently fall to a level of clinical importance, it was from 6 to 50 per cent below normal in the reported series.

The authors concluded that amino acids can be employed parenterally as the only source of nitrogen to maintain positive nitrogen balance. When adequate amounts are given along with sufficient calories, an increase in the total circulating plasma proteins can be obtained.

ELECTRICALLY TRANSCRIBED RADIO HEALTH PROGRAMS

On page 755 of this issue of *THE JOURNAL* appears an announcement of electrically transcribed radio broadcasts for use by county or state medical societies or by approved local groups in their communities. On approval of the local medical society, these transcriptions will be lent to radio stations, health departments, voluntary health agencies, parent-teacher organizations or other community groups. The completion of two series of electrical transcriptions with additional series planned, rounds out the radio service of the American Medical Association to the profession and the public.

The Association has just concluded its tenth annual series of radio network presentations over the network of the National Broadcasting Company. The last eight have been in dramatic form. *Doctors at War* has been of special interest and value to the war effort. A script library of more than eight hundred titles for local use is maintained by the Bureau of Health Education and has been extensively used by the local medical societies and local groups approved by them. Many local and state medical societies have contributed excellent scripts to this library, as have health departments and voluntary agencies.

The electrical transcriptions now made available are an effort to continue the service of the medical profession to the public in the field of health education. With depleted ranks of local medical societies, radio broadcasting becomes more difficult even as it grows in importance with wartime health problems facing the people. These radio transcriptions should be widely used in the health education program of the medical profession.

PENICILLIN FAST BACTERIA

According to Schmidt and his associates¹ of Christ Hospital, Cincinnati, penicillin resistant strains of bacteria are developed as a result of unsuccessful penicillin therapy in experimental animals. Four groups of 10 white mice were injected intraperitoneally by the Cincinnati investigators using 10⁻¹ cc doses of a twelve to fourteen hour broth culture of type I or type III pneumococcus. In the control or untreated group there was a 100 per cent type III mortality within twenty-eight hours. There was a 100 per cent survival in the parallel group given repeated 2,000 Oxford units (10 mg) of penicillin by stomach tube. There was only a 50 per cent survival with half this adequate therapeutic dose (5 mg) and but a 10 per cent survival following a quarter dose (2.5 mg).

Pooled cultures were made from the heart bloods of mice which died from these inadequate doses and injected intraperitoneally into a normal (untreated) mouse. Subcultures from the necropsy blood of this mouse were used to infect 40 new mice. These received the same treatment as the first 40. Thus far the procedure has been repeated for six consecutive groups. By the sixth group passage the pneumococci had acquired sufficient penicillin resistance to be practically unaffected by the originally adequate therapeutic dose, 90 per cent of those given 2,000 Oxford units of penicillin dying within fifty-eight hours. A similar, though less pronounced, penicillin resistance was acquired by type I pneumococci.

To test the permanence of this acquired resistance, the resulting penicillin fast strains were passed daily through normal mice. After the thirtieth serial passage the recovered cultures were still penicillin resistant. The acquired resistance is therefore a fairly stable heredity character in penicillin adapted pneumococci.

Susceptibility of the adapted strains was also tested with sulfapyridine. Infections with penicillin resistant pneumococci responded to sulfapyridine therapy as well as infections with the initial penicillin susceptible parent cultures. This proof that acquired penicillin resistance does not alter sulfonamide sensitivity is the converse of a phenomenon previously reported.² Other investigators have found that the development of sulfonamide resistance does not alter penicillin sensitivity.

Schmidt believes that his data explain the reported clinical failure of penicillin therapy in subacute bacterial endocarditis caused by *Streptococcus viridans*,³ a disease invariably requiring long term treatment. Whether or not the penicillin fast pneumococci can be resensitized to penicillin by the Tsuchiya technique⁴ has not yet been determined.

Current Comment

THE FACTS ON PROCUREMENT OF PHYSICIANS FROM NEW YORK STATE

A criticism¹ which appears as a Supplementary Report of the Council, Part VIII written by the Chairman of the War Participation Committee of the Medical Society of the State of New York, on April 30, 1943, states

The latest information obtainable from the State Procurement and Assignment Committee is as follows:

Number of physicians from New York in service on Feb 1 1943	9,000
Additional listed since February 1	800 to 900
Total	9,800 to 9,900
New York quota for 1942	9,600
New York quota for 1943	2,100
Total	10,700

It is evident therefore that New York has not only met its 1942 quota but is on the way to meeting its 1943 quota.

The official records of the Procurement and Assignment Service are derived from the Adjutant General of the U S Army, the Surgeon General of the U S Navy and the Surgeon General of the United States Public Health Service. Careful tabulations are made from the official lists after the individual physicians' names have been verified against known records. On Jan 31 1943 there were 7,460 physicians on duty with the armed forces from the state of New York, while on March 31, 1943 there were 7,676 physicians on duty from that state. During the months of February and March 1,035 were called to duty from the entire country. Each name credited by the Procurement and Assignment Service represents a physician who left a civilian practice and reported for duty with the armed forces. The discrepancy between the figures cited is doubtless due to the difference between the number of physicians who signified their willingness to serve their country in the armed services and the number actually commissioned and on duty.

THE NURSE TRAINING PROGRAM

Under Medicine and the War in this issue of THE JOURNAL appears a statement by Surg Gen Thomas Parran relative to the new training program for nurses initiated by the passage of the Bolton Act. Under this act nurses' training schools which wish to participate in the program may develop speed-up plans for training nurses—one requiring twenty-four months and the other thirty months. During their training the girls will receive tuition, stipends, maintenance fees distinctive insignia and uniforms. They will be members of a U S Cadet Nurse Corps. Thus they will be provided with a profession, the only obligation they assume is an agreement to make their services available to the government or for essential civilian nursing duties for the duration of the war. Girls who were enrolled ninety days before the end of the war will be permitted to complete their training. Unanimous action of the Congress in passing the Bolton Act was a recognition of the fact

that the shortage of nurses has reached the danger point. Since a high school training is required for entrance on this course, only some 600,000 girls who graduate from high school each year are eligible and more than 10 per cent of all these graduates must enroll in nurse training to reach the goal that has been set for 1943. No one knows better than do the physicians of this country the importance of good nursing service in the care of the sick. Every physician can aid the war effort by urging on every high school graduate who comes to his attention the desirability of participation in the nurse training program.

MIXED SALIVARY GLAND TUMORS

In a recent review of his extensive observation on mixed tumors of the salivary glands, McFarland¹ points out that the long delay in what is regarded as recurrence of these tumors after removal may lead to the belief in the meantime that treatment has been successful "when no good at all has resulted." By "no good at all" he obviously means so far as permanent cure is concerned because the delay in recurrence cannot but be of benefit to the patient, even if he has not been cured. In view of the apparent recurrence of mixed tumors even twenty, thirty or forty years after operation, McFarland asks "Is any patient, once the victim of such a tumor, ever cured?" One answer to this question would be that certainly at least some patients remain practically cured until they die. Here it should be noted, as explained by McFarland, that not every case of a second tumor is a recurrence due to incomplete removal of the first tumor. The probability that new, independent tumors may appear in the same region sooner or later after removal of a tumor can never be excluded. In view of the accepted rarity of metastasis in these tumors, it is of interest to note that recently Mulligan² reviewed 21 cases in which autopsies revealed metastases in the lungs, the liver and other places. McFarland states that after a special study of the results of radiotherapy of mixed salivary gland tumors he did not find a single case in which any real benefit had been obtained from x-rays or radium, and consequently he expresses the belief that it seems useless to attempt to control or modify the growth of these tumors or to postpone recurrence by the use of these agents. This statement and others somewhat similar apply to radiotherapy as practiced in the past. Details of the treatment are not given, possibly in many cases it may have been wholly inadequate. Forms of carcinoma regarded as radioresistant have been found to yield to new methods of radiotherapy, and the possibility that new and improved methods of radiotherapy of mixed salivary tumors at least in certain cases, may prove to be of value should not be overlooked. These tumors are a challenge to surgery and to radiation neither one of which can be regarded as having reached the limits of its usefulness.

1 New York State J. Med. 43: 1109 (June 15) 1943.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

FEMALE DIETITIANS AND PHYSICAL THERAPY AIDES IN MEDICAL DEPARTMENT OF ARMY

Under an act approved on Dec. 22, 1912 the Congress authorized for the duration of the war and for six months thereafter the employment in the Medical Department of the Army of such female dietetic and physical therapy personnel as are considered necessary by the Secretary of War. Regulations have recently been issued under which such appointments will be made (8 Federal Register 7525 June 8, 1943). According to these regulations the director of dietitians or of physical therapy aides will hold the rank of major, a chief dietitian or chief physical therapy aide the rank of captain, a head dietitian or head physical therapy aide the rank of first lieutenant and a dietitian or physical therapy aide the rank of second lieutenant.

Original appointments will be made in the grade of dietitian or physical therapy aide except original appointments made in theaters of operation outside the United States, in which case appointments will be made in such grades as the Surgeon General may deem appropriate. The director of dietitians and the director of physical therapy aides will be designated as such by the Secretary of War for a period of four years, unless sooner terminated. Application for appointment should be made to the Surgeon General who will furnish the necessary blank forms. The same regulations as to marital status will apply to dietitians and physical therapy aides as apply to Reserve nurses, and the same physical standards will be required as are required for appointment in the Army Nurse Corps. Appointments will not be made after the applicant has reached her forty-fifth birthday.

An applicant to be eligible for appointment as a dietitian must have a bachelor's degree from an approved college with either a major in foods and nutrition or in institutional management. In addition she must have completed a training course for dietitians approved by the Surgeon General. Two years of experience in a hospital approved by the Surgeon General may be substituted for the training course but only in case the experience includes diet therapy, planning adequate menus, supervising employees in food preparation and service, controlling food costs, and ordering food supplies and equipment. One year of such experience must have been within the past ten years.

The minimum requirement for appointment as a physical therapy aide will be completion of two years in an approved college with major emphasis on physical education or biologic science, or graduation from an accredited course of nursing, and in addition the applicant must have completed a training course in physical therapy approved by the Surgeon General.

Female dietitians and physical therapy aides employed by the Medical Department of the Army in the continental United States prior to March 31, 1943 may be appointed in the Medical Department of the Army if they meet the physical requirements, are recommended by the commanding officer of the hospital as being suited to the military service and have had training and experience acceptable to the Surgeon General. Similar provision is made for the appointment of female persons employed by the Medical Department in a civilian status as dietitians or physical therapy aides in overseas hospitals prior to March 31, 1943.

An applicant otherwise qualified will be authorized to appear at her own expense at the nearest army station having adequate facilities for completing a final type physical examination. The first assignment of a dietitian or physical therapy aide will

ordinarily be made to a station in the United States, other than appointments made overseas to afford an opportunity to become familiar with military and medical department procedures. When available quarters in kind for dietitians and physical therapy aides will be furnished, with due consideration for their relative rank and standard items of bedroom furniture will be furnished. Dietitians and physical therapy aides will be subsisted under the provisions of existing regulations for the operation of messes for duty and patient personnel in an officer status.

DR. BERENS NAMED CIVILIAN CONSULTANT TO OFFICE OF THE AIR SURGEON

Dr. Conrad Berens of New York has been named civilian consultant in ophthalmology to the Office of the Air Surgeon, the War Department announced on June 26. A graduate of the University of Pennsylvania, Dr. Berens is chairman of the American Board of Ophthalmology, chairman of the Section on Ophthalmology of the American Medical Association, director of the New York Eye and Ear Infirmary and professor of ophthalmology at New York University and the author of a textbook on ophthalmology. Beginning in 1939, Dr. Berens served on the committee to select and train civilian pilots. He served as a major in the last war with medical research and examining units. Starting at the School of Aviation Medicine at Mitchel Field, New York, his work necessitated assignment to England and France.

FALSE RUMOR CONCERNING ENLISTMENT OF ARMY SPECIALIZED TRAINING PROGRAM TRAINEES

The Headquarters of the Sixth Service Command, Chicago, has requested that steps be taken to counteract all stories that enlisted men assigned to the Army Specialized Training Program will be required to remain in the Army longer than those not in the program.

Reported rumors from various service commands have stated that A S T P trainees are compelled to remain in the Army from five to ten years after the present emergency. This rumor is completely false in that the term of enlistment is in no way changed by assignment to the A S T P. All A S T P men are in the Army under the same conditions as any other enlisted man, that is, the government has inducted him for the duration of the emergency and six months thereafter.

CAPTAIN DISKIN RECEIVES AWARD

Capt. Herman E. Diskin of the Army Medical Department has been awarded the Legion of Merit for exceptionally meritorious service in combat on Guadalcanal. The award was made by Lieut. Gen. Millard F. Harmon, commander of the army in the South Pacific, on May 11. Captain Diskin, according to the Kalamazoo (Mich.) Gazette, together with a non-commissioned officer, made a reconnaissance through an enemy-held territory to establish a route of evacuation to casualties of an infantry regiment, which route was a prime factor in the swift evacuation of casualties during a subsequent advance of the regiment. Captain Diskin, who graduated from Wayne University College of Medicine, resides in Detroit and is stationed at Fort Custer, Michigan from November 1940 to January 1942.

NAVY

MALARIAL CONTROL

The Office of Malaria Control in War Areas reports that Anopheles breeding places at Miami Beach Fla. where most of the hotels and large apartment houses are taken over by the Army, have been reduced to an all time low.

Comdr O I Brown and Comdr J S Barr, MC U S N, were assigned to represent the Bureau of Medicine and Surgery in a conference with representatives of the Surgeon General of the Army and the U S Public Health Service on malarial control.

An engineer from the Office of Malaria Control in War Areas will direct airplane dusting operations to control Anopheles quadrimaculatus breeding in the Potomac River adjacent to war establishments below Washington. An entomologist from this office will coordinate inspection services which will be carried on by the health departments of Virginia, Maryland and the District of Columbia in order to check the effectiveness of the dusting operations.

SURGICAL SUPPLIES AND VICTORY KITS

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, recently presented the U S S *Alabama* and the U S S *Mobil* with surgical supplies to help equip battle dressing stations and through the cooperation of Victory Kits Inc. 276 victory kits were sent to the U S S *Iowa* and the U S S *Mobil* for distribution to rescued seamen and members of the crew needing them.

CIRCULATING LIBRARY OF MOTION PICTURES

The circulating library of motion pictures referred to in THE JOURNAL, June 5 1943, page 381 is not intended for civilian use except under special authorized instances. The Bureau of Medicine and Surgery of the Navy in Washington D C has already received a number of requests for these films which cannot be granted. The director of the division of publications of the Bureau of Medicine and Surgery has suggested that civilian individuals and agencies do not request navy medical films.

NAVY DISCONTINUES HOSPITAL FUND DEDUCTION

President Roosevelt has approved the bill H R 2584 which abolished on July 1 the 20 cent a month deduction from pay of naval personnel for support of naval hospitals. The full responsibility for supporting the hospitals is placed on the government appropriations, as is the case with army hospitals.

NAVY PERSONALS

Capt Paul W Wilson MC U S N, recently gave a series of lectures at the Mayo Foundation, Rochester Minn. on tropical diseases.

Lieut (jg) Harriet J Davis W-V (S) U S N R has reported for duty to the Bureau of Medicine and Surgery and has been assigned to the naval dispensary in Washington.

CIVILIAN DEFENSE

EMERGENCY MEDICAL SERVICE FOR WAR PLANTS

The majority of American war plants are unprepared to provide emergency medical attention for victims of air raid explosion or other wartime plant disaster surveys by the Office of Civilian Defense and the U S Public Health Service disclose. James M Landis, director of Civilian Defense, said on June 30 that reports indicate only about one out of five of the larger war plants has made arrangement for hospitalization of war disaster victims and that among smaller plants the proportion is even less. 'No one expects industrial plants to provide facilities themselves to care for victims of large scale disasters,' Mr Landis said, 'but these facilities can be made available in almost every community and war plants should set up before the need for them arises definite plans and arrangements for providing emergency medical attention for their personnel.'

In a study conducted by the U S Public Health Service in 1940 it was found that in plants of more than 100 employees only 20.3 per cent of the workers had access to a full time plant physician, 27.6 per cent to a part time plant physician while 52.1 per cent had none. In plants of less than 100 employees 9.4 per cent of the workers had no plant physician service.

Industrial plants are seldom able to provide hospital care for victims of large scale disasters unless they utilize the facilities of the community,' Mr Landis said, 'but all can provide a staff trained and equipped to give efficient first aid to the victims of disasters. As preparation for an emergency, all war plants should make definite arrangements for providing expert medical service for injured personnel by utilizing community medical resources organized under chiefs of Emergency Medical Service of the Office of Civilian Defense. In almost every community in the United States community medical facilities have been mobilized for war purposes by the Civilian Defense Emergency Medical Service. These facilities will serve the whole community including its war plants but their effective utilization by industry demands careful advance planning.'

Hospital and private ambulances will rarely be adequate to care for the large number of persons who may be injured in a major disaster. In most communities the Emergency Medical Service has made a survey of available ambulances and has arranged to supplement them with converted panel trucks, station wagons and other vehicles in the event of emergency. Industrial plants should provide means of converting some of their own vehicles into ambulances and should plan their disaster operations with the chief of the local Emergency Medical Service so that necessary ambulances can be assigned to them when they are needed or their own vehicles used elsewhere in case of an emergency that does not involve their own plant.

To care for emergency casualties hospitals must prepare for them in advance by providing a supply of temporary beds to be set up in corridors and elsewhere and making other advance arrangements. Industrial plants should know under a pre-arranged plan worked out with the chief of the Emergency Medical Service what hospitals are to be used for casualties from the plant and how many can be sent to each, thus assuring prompt and adequate attention for those who must be hospitalized. None of these arrangements can be made swiftly after a disaster has struck.

Proper identification of casualties is another thing which must be planned in advance. Official Civilian Defense identification tags and casualty record books are available from the local chief of the Emergency Medical Service. Casualty stations in which injured may receive preliminary treatment before being discharged or sent to hospitals should be established both inside and outside the plant.

Another major problem which must be dealt with in advance or any catastrophe is that of admittance of doctors and other members of the Emergency Medical Service to plants. Industrial plants must depend on community facilities for emergency service but, unless arrangements have been made in advance, doctors, ambulance drivers and other workers dispatched by the chief of the Emergency Medical Service or other authorities will be unable to secure entrance into the plants. With the assistance of War Department service commands Mr Landis said personnel of Civilian Defense Emergency Medical Service are being investigated and certified with proper credentials so that they may be admitted to war plants in emergency.

MISCELLANEOUS

NEW PROGRAM TO PROVIDE TRAINING
FOR NURSES

THOMAS PARRAN

Surgeon General, U S Public Health Service

The Bolton Act, approved on June 15, provides "for the training of nurses for the armed forces, governmental and civilian hospitals, health agencies and war industries, through grants to institutions providing such training, and for other purposes" (Public Law 74). The provisions of this war emergency law should aid in alleviating the serious nursing shortage throughout the country.

The act was drafted with the full cooperation of nursing institutions, hospitals, the nursing profession and governmental agencies. Need for the measure was emphasized by the Health and Medical Committee, Federal Security Agency, of which Dr. Hyman Abel of Louisville, Ky., is chairman. Representatives of many hospitals and leading hospital associations also have urged that some such program be established by the government. The bill was passed by both houses of the Congress without a dissenting vote, and an appropriation sufficient to implement the program has been approved. I hope for the participation of all eligible schools and immediate intensive recruitment of large class sizes.

A decentralized plan of operation has been established by the U S Public Health Service, the agency designated by Congress to administer the act. Training institutions will submit plans meeting the several requirements of the act, and funds will be paid to institutions when plans are approved. Subject only to meeting minimum requirements, full responsibility for carrying out the nurse training program remains as it present, with the training school.

An advisory committee of not less than five members is provided by the act to assist the Surgeon General of the U S Public Health Service in formulating rules and regulations to carry out the purposes of the act. The Federal Security Administrator has named nine persons representing "the nursing profession, hospitals and accredited nurses training institutions."

Members of the Advisory Committee are Dr. Oliver C. Carmichael, president of Vanderbilt University, Nashville, Tenn.; James A. Hamilton, director, New Haven Hospital, New Haven, Conn.; Miss Marion Howell, dean, Frances Payne Bolton School of Nursing, Western Reserve University, Cleveland; Sister Helen Jarrell, dean, Loyola University School of Nursing, St. Bernard's Unit, Chicago; Dr. Hyrum Leo Marshall, professor of public health, University of Utah, Salt Lake City; Rev. Fr. Alphonse M. Schwitalla, dean, St. Louis University School of Medicine, St. Louis; Miss Isabel M. Stewart, director, Division of Nursing Education, Teachers College, Columbia University, New York; Miss Margaret Tracy, director, School of Nursing, University of California, Berkeley; Miss Anna D. Wolf, director, School of Nursing, Johns Hopkins Hospital, Baltimore.

The first meeting of the committee was held in Washington on June 25 and 26 (*THE JOURNAL*, July 3, p. 683). Regulations growing out of decisions reached at this meeting will be published promptly.

Student nurses who receive training under the Bolton Act will be members of what the Advisory Committee voted to designate "U S Cadet Nurse Corps." These students will be provided with tuition, stipends, maintenance, fees, distinctive insignia and uniform, including a street uniform. Graduate nurses taking refresher and postgraduate courses provided by the new act as an extension of the "Training for Nurses" (National Defense) Act now in effect will not wear street uniforms.

The law sets forth rather fully the requirements which must be submitted for approval by the institution wishing to participate in the program. The institution has the choice of two speed-up plans for training, one requiring twenty-four months, the other thirty months.

Stipends to students under both plans will be not less than the following monthly rates: \$15 for the first nine months of study,

\$20 for the following fifteen to twenty-one months of combined study and practice, depending on the curriculum of such institution and \$30 for the period following the period of combined study and practice and prior to graduation. The government institutions pay for stipends given students during the first nine months, for uniforms and insignia, and for reasonable tuition and fees throughout the courses of study and training. Institutions pay stipends during the final period of training and provide maintenance after the first nine months.

During the terminal period of training the institution will either afford student nurses under the plan an opportunity to complete their course of training until graduation, paying them a monthly stipend of not less than \$30, or transfer the student for training to some other institution if such training may be credited toward graduation. In the latter case the institution to which the student nurse is transferred agrees to pay her a monthly stipend of not less than \$30 until graduation.

Funds to institutions will be paid quarterly in advance in the amounts estimated in order to enable institutions to carry out the provisions delegated to them by the act. Subsequent allotments can be increased or decreased, depending on how accurate the initial estimates have proved to be.

In return for training in the profession of nursing without cost to themselves, student nurses who enroll as members of the U S Cadet Nurse Corps agree to make their services available to the government or for essential civilian nursing duties for the duration of the war. Any student nurse who has enrolled since Jan. 1, 1941 in a school of nursing participating in the federal plan is eligible to join the corps.

Students who enrolled in the corps ninety days prior to the end of the war will be permitted to complete their training. Thus, members of the corps need not fear that their training will terminate before the course is completed.

The shortage of nurses has reached the danger point. Civilian hospitals are carrying peak loads. Some of them have closed units because they are unable to secure sufficient numbers of nurses. In industrial boom areas, nurses are needed for hospitals, war plants and public health services. Health agencies in all areas report a critical shortage of nurses.

To reach the 1943 goal of 65,000 new student nurses, which is actually somewhat short of the real need, more than 10 per cent of the approximately 600,000 girls graduating from high school each year must be secured.

In the new training program student nurses will be provided with a lifetime profession and at the same time have the satisfaction of gaining recognition for rendering a national war service.

SURGICAL MISSION TO RUSSIA

At the close of the Hunterian Oration before the Royal College of Surgeons of England on May 26 the President, Sir Alfred Webb-Johnson, admitted two new honorary fellows: Col. Elliott C. Cutler, Moseley professor of surgery at Harvard University and chief surgical consultant to the United States Army, and Dr. W. G. Penfield, professor of neurology and neurosurgery at McGill University, Montreal. These two surgeons, with Col. Loyal Davis of the U S Army, will be taking part in the forthcoming Anglo-American Surgical Mission to Russia. The British section, which is proceeding under the joint auspices of the British Council and the Medical Research Council, will consist of Surg. Rear Adm. G. Gordon Taylor, Major Gen. D. C. Monro, professor of military surgery at the R. A. M. College, Milbank, Mr. E. Rock Carling and Mr. R. Watson-Jones. The aims of the mission are to study the results of war surgery in Russia and to explore the possibility of extending medical relationships between the two countries. During the visit to the Soviet Union Surg. Rear Admiral Gordon-Taylor, the senior vice president of the Royal College of Surgeons, will admit to the honorary fellowship two Russian surgeons: Dr. Nikolai N. Burdenko, director of the Operative Surgery Institute, Moscow University, and surgeon in chief to the Red Army, and Dr. Sergei S. Yudin of the Sklifassovski Hospital for Traumatic Diseases, Moscow.

SOVIET PATRIOTS RESTORING PUBLIC HEALTH SERVICES

GREGORY SHAYKHON

I conversed recently with Nadzhdia Demidova, just back from Krasnodar, whither she was delegated by the Council of People's Commissars, Russian Soviet Federated Soviet Republic, to supervise the registration of public health service in liberated territory. She spent three months there.

Thanks to the united effort of local public health workers," Demidova said, and extensive cooperation of the local inhabitants, we succeeded in a comparatively short time in eliminating to a considerable extent the consequences of terrific destruction and damage caused by forces of occupation to Soviet public health institutions.

According to data cited by Demidova, as a result of three months' effort the following work was accomplished by the end of April in Krasnodar where the majority of the medical institutions were depleted, blown up, burned or converted into stables by Germans. One hundred and fifty-four rural eighteen urban and five children's hospitals received new or restored premises; all rural dispensaries on liberated territory were reopened. Demidova, a veteran worker of the health commissariat, recounted vast damage caused to public health institutions. A new well equipped hospital in the village of Uspenskaya was converted by the Germans into a stable after they robbed it of all equipment. The Gestapo with its terrible torture chambers established headquarters in the Armavir Maternity Home.

Demidova reported a number of facts illustrating the courage and fortitude of Soviet patriots and medical workers who saved much of the property of health institutions and many buildings. The brave personnel of City Hospital No. 2 in Armavir averted destruction of new buildings of the hospital with its 200 patients which Germans retreating under the onslaught of the Red Army were preparing to blow up. Informed of methods of the Hitlerites, many directors of hospitals, sanatoriums, children's creches and mother and child health centers took measures to forestall them and save public property. They gave hospital linen, drugs, surgical instruments, cattle and auxiliary farms to their workers for safekeeping. As the Germans were expelled, all property was returned to the institutions despite the fact that receipts had not been given. This, according to Demidova, was done by Dr. Catherine Fedoseyeva, the wife of a colonel of the Russian Army who fought courageously during the first world war. Dr. Fedoseyeva succeeded the chief physician who left with Red Army units. Despite her 73 years, this aged woman doctor at the cost of heroic effort took every precaution to save scores of sick children undergoing treatment in a sanatorium. They were children of local functionaries who joined the Red Army. Learning that the Germans were planning the slaughter of innocent children, the doctor resorted to a ruse. She destroyed the record cards, isolated the children in a special ward and when the Gestapo agents called they were told that this was the ward for infectious diseases.

When the Germans entered, Dr. Fedoseyeva called on some members of her staff to help preserve supplies of linen, instruments, drugs and cattle. Thus she saved fifteen cows.

The people of the village of Labinskaya tell with pride about the chief doctor of the local hospital, Maria Dyakova, who risking her life saved 250 Soviet citizens doomed by Germans to death. Numerous examples said Demidova can be cited of equal courage among Soviet health workers in Krasnodar.

After the German retreat these patriots set to work with redoubled energy to restore the health services. They were short of linen, instruments, furniture and equipment for hospitals and children's institutions. Active groups left in town organized a collection of these articles from the population. Simultaneously hygiene inspectors made rounds of all homes

to see if there were any sick. A number of cities—Armavir, Krasnodar, Kropotkin, Maikop, Labinskaya—were infected with typhus and other diseases. Provision of hospital accommodations for all sick, energetic work of antiepidemic squads sent to the center for reopening of dispensaries, polyclinics of hygiene and antiepidemic centers, bath houses and laundries, combined with a number of prophylactic measures brought desired results. Already in April there were no epidemics, which had been widespread during the German occupation.

MEDICAL AND SURGICAL RELIEF COMMITTEE

The St. Paul chapter of the Medical and Surgical Relief Committee of America recently shipped by diplomatic pouch to the Soviet Red Cross 8,000 sulthiaguanidine and 9,000 sulthiazole tablets.

Five emergency medical kits for ambulances, a complete operating set, an x-ray unit and a fluoroscope were recently shipped by the Medical and Surgical Relief Committee of America to the French Red Cross for distribution to French hospitals in the North African area.

The committee has been requested to send to China a portable x-ray set complete with generators and photoroentgenographic unit to combat tuberculosis among the Chinese soldiers. There is no special hospital for tuberculous soldiers in all of China according to Col. Wesley K. C. May of the New Life Movement in China.

The headquarters of the Medical and Surgical Relief Committee of America are at 420 Lexington Avenue, New York City. Among the many volunteers and contributors recently listed by the committee are the Doctors Aid Corps, Atlanta, Ga., and the Woman's Auxiliary to the Georgia Medical Association, to the Hennepin County Medical Society, Minneapolis, to the North Carolina State Medical Association, to the New Hampshire State Medical Society, to the Medical Society of the State of New York and to the West Virginia Medical Association.

THE "BLITZ" ON GUY'S HOSPITAL

Abstract of an article by P. M. F. Bishop, Deputy Superintendent, Guy's Hospital, London, published in Guy's Hospital Gazette, March 20, 1945.

On Sept. 15, 1940, early in the battle of London, a bomb crashed through the dome of Hunt's House. The great staircase beneath was demolished. The only casualty was a medical officer who concussed and bleeding from a badly lacerated scalp, had to be lowered from a fourth floor window down a fireman's ladder. Sixty patients were rescued from the first and second floor wards by the fire escape. From that day on for many months access to about two hundred and fifty beds was denied us and for more than a year after the staircase had been partially restored every patient and all the paraphernalia of the wards had to be carried up and down until one of the lifts could be repaired.

Guy's passed through the night of the great fire not wholly unscathed. Though it was left standing, the flames could not be prevented from setting fire to the residential college and to the high voltage x-ray department at the top of the already bomb-shattered Hunt's House. Moreover, of three or the few high explosives that fell in London that night, one did irreparable damage to the surgical block, another by bursting in a subway reproduced many of the curious phenomena resulting from blast in a confined space, and the third smashed scores of windows in that glass house, the dental department. Fortunately, once again there were only minor casualties. All the patients had to be evacuated by ambulance to the country, and finally all of the staff but twenty and some of the more valuable and portable pieces of equipment were removed to places of comparative safety. Thus for the first time in its history, Guy's closed its gates to the sick for a few brief hours. Next morning, however, the dauntless outpatient could be seen pick-

ing his way through the debris to consult his doctor. The night had brought excitement, danger and damage but also miraculous escape, and in the aftermath came an expression of friendship in need, for the high voltage x-ray plant was replaced from across the Atlantic and installed in the Guy's U. S. Army hospital at Seel.

On the third historic night of April 16 a canister of incendiaries emptied its bombs over the hospital. Everything that could be moved was taken out of the burning building. Portraits of eminent ancestors were torn from the walls of the fine eighteenth century mahogany staircase, chairs and tables carried from the governors' committee room, personal belongings rescued from the superintendent's house, files and records taken from the counting house and x-ray equipment was gently disentangled from the surgical radiology department until at last there was nothing more to be done.

Guy's admitted many air raid casualties. Except for a few scattered makeshift wards, such as the hall of the message department, the unbombed wing of an L shaped ward in the surgical block, and later the basement of the new York psychiatric clinic, the use of which was made necessary by the demolition of the staircase of Hunt's House, all patients both civilian sick and air raid casualties were accommodated in one block. In this same building casualties were received, resuscitation was undertaken and in its emergency underground theaters operations were performed.

Cases are received by a student "ambulance teler," who checks the number of stretchers and blankets brought in from each ambulance and enters into his record the Guy's serial number of each casualty and the site of the incident which the ambulance has attended. He issues to each casualty an M. P. C. 47 envelop in which all the case reports are collected and finally dispatched to the Ministry of Pensions Records Office. On this envelop the Guy's serial number has previously been inscribed. His colleague replaces from stock to each ambulance attendant the number of stretchers and blankets brought in with the casualties. In the reception hall the casualty is inspected by the reception officer and his staff of house officers, students, sisters and nurses and is at the same time interrogated by the almoner with regard to name, address and next of kin. Routine antitetanus serum is given at this stage, but otherwise the patient is disturbed as little as possible except to insure that hemorrhage is controlled and fractures immobilized. Relatives or police are directed to the almoner's office. Relatives and friends are offered a "shakedown" for the night until the "all clear" sounds.

The casualty passes quickly to the resuscitation ward, where he is given reassurance, warmth, morphine if necessary and a cup of tea and a cigaret unless an abdominal injury is suspected. At regular intervals the pulse rate and blood pressure are recorded. In more serious cases, unless these become steady and the color improves in about half an hour, a transfusion is given—of blood if the loss of it is evident or surmised, otherwise of plasma. In the early days too many patients were transfused and too much blood was given. More than 2 pints seldom diminishes the operative risks further. Within half an hour or so of the admission of a batch of casualties the surgical officer in command with one or two ward clerks to take notes proceeds quickly on a round of assessment. Patients are disturbed as little and as infrequently as possible and an atmosphere of bustle is discouraged. Clothes are loosened only to give access for adequate examination of injured parts. Fitness for operation is judged on improved color, steady pulse and a systolic blood pressure maintained at about 100 mm for half an hour. Resuscitation is required in the majority of cases only for two to six hours before operation is embarked upon. The surgical officer in command arranges and writes up on the blackboard an order of operations. He seldom operates himself.

Of casualties admitted, from 40 to 50 per cent come to operation. The average time required for each operation is about an hour, which includes undressing the patient under the anesthetic and washing off the ingrained dust of collapsed buildings. In eight hours 30 to 40 cases can be dealt with by four surgical teams. To work longer than this without relief is to lose efficiency. To delay operations beyond this time is to run

increasing risks of sepsis. Thus more than 75 casualties should not be admitted by a hospital disposing of four surgical teams.

The quality of the anesthetic will in some cases determine life or death of the patient. General anesthesia is the rule. Induced by small doses of pentothal sodium, it is maintained by gas, oxygen and minimal quantities of ether. With a low blood pressure spinal anesthesia is dangerous, and local anesthetics are not suitable for gross wounds and multiple injuries.

Soft tissue wounds are treated certainly within twelve hours, mostly within eight. Careful excision followed by packing is preferred to primary suture, which is rarely performed. Distal limb wounds are immobilized in plaster, but shoulder and hip spicas are found too time consuming. Multiple wounds from glass injuries, of which there were a surprisingly large number, are usually dealt with by multiple operators.

Experience underlined two important general principles speed in operating, often achieved by two surgeons working simultaneously on 1 case, and minimal blood loss with immediate replacement by drip transfusion in the theater or on returning to the ward.

By noon on the following day about two thirds of the night's casualties were evacuated to base hospitals. Cases retained included postoperative abdominal and chest injuries, certain cases of fractured ribs and blast injuries, all severe head injuries, cases in plaster with a precarious peripheral circulation, fractures in extension with blood supply or adequate immobilization in doubt (these cases were often transferred to a Balkan beam, and it was found that, on the whole, fractured femurs did not take kindly to an early second move), and amputations and gross multiple injuries in poor condition.

Less interference in the reception hall, fewer transfusions, less blood, bed rest, dimmed lights, warmth, reassurance, a cup of tea and a cigaret became the rule for the patients. Less bustle, less rigid assignment of duties, less issuing of orders, more reliance on "blitz" matured common sense and individual initiative became the practice for the staff. We worked as a team, not as a platoon.

PUBLIC HEALTH UNDER HITLER

NPD, Germany, April 1, states that apart from military and economic problems a host of medical and above all hygienic questions have been raised as the result of the occupation of the vast eastern territories by the German armed force. Whether the soldier penetrates into a region in order to conquer it or whether he wins a battle there and passes through it, he will always come in close contact with the life of the soil, with its plants, animals and human beings. He cannot avoid this contact even during the most violent fighting, but even less when he is deploying in the terrain preparatory to battle or occupying it after a victorious fight. According to the nature of the subsoil, the soldier enters a "health area" or a "disease area."

According to Transocean, France, of March 23, in order to neutralize the effect of the Anglo-American blockade on the health of the French people a number of factories have been opened with the approval of the government. These are, in the first instance, manufacturing vitamins for children and aged people. Vitamin A, for instance, is manufactured on a large scale at Marseilles from fish liver. The distribution of vitamin is in the hands of the Secours national.

A private informant of *Svenska Dagbladet* of March 24 reports that epidemics are again raging in the Baltic countries. Starving wild dogs come to the Baltic countries from occupied Russia and spread disease, often attacking people. Typhus, which was never properly mastered in many Ostland districts, is again raging violently. Delousing must be strictly observed by travelers, and before crossing Germany's frontier a repeat medical examination is required.

According to the press in Riga, foot and mouth disease is raging around Riga, presumably spread by infected hay imported from the Ukraine.

ORGANIZATION SECTION

OFFICIAL NOTES

ELECTRICALLY TRANSCRIBED RADIO HEALTH PROGRAMS

The Bureau of Health Education announces the first two series of electrically transcribed radio health programs for use at state and county medical societies as authorized by the Board of Trustees of the American Medical Association.

Two sets of transcriptions are ready for local use. They are as follows:

(a) "American Medicine Serves the World at War." This is a series of six programs with the following titles and broadcasters, each broadcast being in interview form the physician being interviewed by Harriet Hester:

- Health and Sanitation Problems in Newly Established Wartime Communities by H. H. Shoulders, M.D.
- The Treatment of War Casualties by Rear Admiral Harold W. Smith
- Surgical Procedures in Wartime by Edward J. McCormick, M.D.
- Medicine and Public Health in Hawaii at War by Forrest J. Pinkerton, M.D.
- Civilian Medical Care in Time of War by Edward H. Cary, M.D.
- Public Health Programs in Wartime by Warren F. Draper, M.D.

(b) "Before the Doctor Comes," a series of sixteen radio broadcasts in which Drs. Austin E. Smith, Edwin P. Jordan, and W. W. Bauer are interviewed by Harriet Hester or June Merrill on the following topics:

- 1 The Child With Snuffles—The Child With a Sore Throat
- 2 The Child With a Cough

- 16 Immunization

The electrically transcribed programs can be borrowed by the county medical societies or state medical societies in *complete sets only* if they will make the necessary arrangements with the local radio station. The series "American Medicine Serves the World at War" requires no local participation, since each broadcast is a complete interview recording. The series "Before the Doctor Comes" can be used without local participation in ten minutes of radio time or with local participation in fifteen minutes; in the latter instance full instructions accompany each set of records. There will be no charge for any local use of the records, but groups not of the medical profession must be authorized by the local medical society to use the transcriptions. The only cost to local groups will be a nominal charge ranging from 50 cents to \$1.50 depending on distance from Chicago for return express charges. It is necessary for a successful carrying through of transcription loan projects that loan sets be returned promptly.

Reservations for use of these transcriptions may be filed with the Bureau of Health Education at once specifying date desired. Ten sets of each series are available and will be lent in the order in which reservations are received.

W. W. BAUER

SUMMER HEALTH HINTS

The next three programs for the series of broadcasts over WLS on Thursdays at 2:45 p. m. under the title "Summer Health Hints" will be as follows:

- July 15 Poison Oak or Ivy
- July 22 Keeping Cool
- July 29 Light Summer Meals

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—H. R. 2935 has passed the House and Senate making appropriations for the Federal Security Agency and related independent agencies for the fiscal year ending June 30, 1944. In the Senate the proviso was eliminated prohibiting the use of any appropriation for the Children's Bureau for the promulgation or carrying out of any instruction, order, or regulation relating to the care of obstetric cases which discriminates between persons licensed under state law to practice obstetrics. The bill then went to conference and the conferees agreed to reinsert the proviso with the following addition: *Provided further* that the foregoing proviso shall not be so construed as to prevent any patient from having the services of any practitioner of her own choice paid for out of this fund so long as state laws are complied with. Thereafter the House of Representatives by a vote of 212 to 152 acquiesced in the recommendation of the conference committee. The Senate likewise agreed to the recommendation of the conference committee. The bill therefore needs only the approval of the President to become a law and will contain the two provisos recommended by the conference committee. H. R. 2996 has passed the House and Senate and awaits the approval of the President making appropriations for the military establishment for the fiscal year ending June 30, 1944. As passed by the House this bill provided

that no appropriation contained in it "shall be available for any expense incident to educating persons in medicine (including veterinary) or dentistry whose instruction in degree-granting colleges or universities as students in such professions cannot be completed in two years or who are not enlisted in the Army of the United States." In the Senate this proviso was deleted from the bill and the House thereafter concurred in the action taken by the Senate. S. 1130 has passed the Senate providing for the care of children of mothers employed in war areas.

STATE MEDICAL LEGISLATION

Illinois

Bill Passed—H. 802 passed the Senate June 30. It proposes to amend the medical practice act by providing that the entry of a decree by any court of competent jurisdiction establishing the insanity of any person holding a license to practice medicine shall operate as a suspension of such license until such time as a committee of physicians shall find that the licensee has been restored to sanity.

Bill Enacted—S. 167 was approved June 25. It provides for the creation of a state board of health to take over the duties of the department of public health.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Nutrition Clinic Study—The National Research Council recently sponsored the visit of a group of scientists to the Nutrition Clinic at the Hillman Hospital, Birmingham, to study the work of Dr. Tom D. Spies with a view to determining the possibility of extending corn meal to meet special nutritional needs of the South. The visit was said to be financed by private contributions and the research council. Among the group were Dr. Russell M. Wilder, Washington, D. C., Dr. William H. Schell Jr., Bethesda, Md., Robert I. Griggs, Ph.D., Elmer M. Nelson and Frank I. Gundersen, Ph.D., Washington, Charles G. King, Ph.D., and Robert R. Williams, Ph.D., New York, and Dr. James S. McLester, Birmingham.

CALIFORNIA

Investigation of Encephalitis—The Weekly Bulletin of the California State Department of Public Health reported that a number of cases of encephalitis in several counties were investigated during April. The ages of the patients ranged from 2½ months to 49 years. Laboratory reports indicated that 1 case was of the severe St. Louis type of encephalitis.

Women's Court Created for Sex Offenders—The San Francisco City Separate Women's Court has been established in the Health Center Building, 135 Polk Street, San Francisco, to meet the problem of the professional prostitute, streetwalker and other sexually promiscuous women who are arrested by the police department. Prior to the opening of the Separate Women's Court these women were housed in the women's section of the San Francisco City Prison. During their confinement first offenders were placed with habitues and frequently with other criminals, thus affording an excellent opportunity for promoting the maladjustment of the first offender. The objective of the new court is to assist in the segregation of the various cases referred by the police department on the basis of a previous history of sex offenses. First offenders are separated from habitues and criminal cases. The objectives in the Separate Women's Court are to render an entirely individualized case study plan. Every effort is made to provide means for adequate referral at those first offenders who present a potentiality of reeducation and readjustment. Detailed case study work is done by three social service workers assigned to the court. Assembled data are referred to the presiding judge with recommendations for disposition of the case so as best to serve the interests of society and the individual. Persons who present no potentiality are subjected to prolonged confinement in accordance with the provisions of the law dealing with prostitution. Individual quarters are provided for each case under custody of the Separate Women's Court and the cases are held under observational quarantine by the health department for seventy-two hours. During the quarantine medical examination is provided by the health department and a complete social case history is secured by the social workers. If the woman is found to be infected she is referred to the health department quarantine treatment clinic and held under custody of the sheriff's department. If not infected the woman is released from quarantine and a disposition made by the judge of the Separate Women's Court. The personnel of the Separate Women's Court consists of a judge, a medical coordinator, a deputy district attorney, a woman physician, a registered nurse, three social workers, four police officers, one court reporter, one court clerk, a bailiff and two general clerk stenographers. Dr. Richard A. Koch, San Francisco, chief of the division of venereal diseases of the department of health, is medical coordinator. Judge Clarence Morris is the presiding judge in the court.

IDAHO

Personal—Dr. Alan L. Hart, Boise, consultant in tuberculosis for the state department of public health and the Idaho Tuberculosis Association, has been granted a leave of absence by the state department to accept a temporary assignment as a genologist at the induction center for the armed forces in Idaho. —Dr. Charles Sanford Allen, Boise, was recently named medical superintendent of the Nampa State School, succeeding Dr. Charles R. Lowe, Nampa. —Dr.

Paul R. Eusign has resigned as director of the city and county health unit in Boise to accept a position as pediatric consultant of the division of maternal and child health of the Georgia Department of Public Health.

ILLINOIS

New Director of Maternal and Child Hygiene—Dr. Hugo V. Hullerman, deputy commissioner of health and director of maternal child health of the Peoria City Department of Health (THE JOURNAL, July 11, 1942, p. 892), has been appointed chief of the division of maternal and child hygiene of the Illinois Department of Public Health. He succeeds Dr. Fred L. Adair, who was recently called to Washington, D. C., to become chief of the division of medical needs of the civilian food requirements branch of the Food Distribution Administration of the U. S. Department of Agriculture. Dr. Adair had served as chief of the state division since March 1, 1942 (THE JOURNAL, March 14, 1942, p. 907). Dr. Hullerman had been chief of the state division of local health administration when he joined the Peoria department of health.

Chicago

Courses on Electrocardiography—The cardiovascular department of Michael Reese Hospital announces a course on electrocardiography to be held August 16-28 under the direction of Dr. Louis N. Katz, director of cardiovascular research. Designed for the general practitioner, emphasis will be placed on chest leads and on the importance of the electrocardiogram in coronary sclerosis and myocardial infarction. Additional information may be obtained from the Michael Reese Hospital.

Dr. Victor Johnson Joins American Medical Association—Dr. Victor Johnson, associate professor of physiology and dean of students in the division of biological sciences, University of Chicago, on July 1 became secretary of the Council on Medical Education and Hospitals of the American Medical Association. Dr. Basil C. H. Harvey, who retired in September 1940 after thirty-eight years as a member of the faculty of the university, will return to active duty as acting dean. He had been dean of students in the division from its establishment in 1931 and dean of medical students since 1932. Dr. Johnson graduated at the University of Chicago School of Medicine in 1939 and has been a member of the physiology department since 1929. He is co-author with Anton J. Carlson, Ph.D., of "Machinery of the Body."

LOUISIANA

State Medical Election—Dr. Valentine H. Gault, New Orleans, was chosen president-elect of the Louisiana State Medical Society at its meeting on May 3 and Dr. Charles C. De Gravelles, New Iberia, was installed as president. Dr. Paul T. Talbot, New Orleans, is secretary-treasurer. The next annual session will be held at New Orleans, April 24-27, 1944.

Personal—Dr. Richard O. C. Green, Alexandria, formerly director of the Rapides Parish Health Unit, has been named to a similar position with the Webster Parish Health Unit, succeeding Dr. Edmond G. Klamke, Minden. —Dr. George W. Games, Tallulah, was presented with a certificate of fifty years in the Masonic Lodge by the Grand Lodge of Louisiana and a pin for fifty years' service.

MICHIGAN

Recommend Increase in Dues to State Society—At a special meeting of the Saginaw County Medical Society recently a resolution was adopted recommending that the dues of the state medical society be increased up to a maximum of \$10 a year. It was stated that the increase would be sufficient to provide additional facilities and services requisite to the well being of the medical profession of Michigan which cannot be supplied on the present inadequate dues. The state dues are now \$12 a year.

Health Program for Imported Jamaicans—The county health department in cooperation with the Saginaw County Medical Society and the state department of health have initiated a concentrated program to prevent the spread of contagious diseases suspected among the Jamaicans who are imported to work in the sugar beet fields, new arrivals reported June 11. Under a four point program the group will be given x-ray examinations and blood tests in an effort to check tuberculosis and venereal diseases, and stool specimens will be analyzed to detect typhoid and dysentery. It is pointed out that the housing situation is satisfactory because of the new housing at Prairie Farm. A large number of persons, however, are living in houses which are absolutely below standard, it is stated.

MINNESOTA

State Medical Election—Dr Elmer M Jones St Paul was elected president of the Minnesota State Medical Association at its annual meeting, May 17, and Dr Richard R Crammer Minneapolis and Melvin S Nelson Granite Falls vice presidents. Dr William H Condit, Minneapolis is treasurer and Dr Benjamin B Souster St Paul secretary. The annual meeting in 1944 will be held in Rochester at a time to be designated by the council.

Personal—Reginald C Sherwood Ph D St Paul food chemist has been appointed by Dr Russell M Wilder as his assistant chief in the civilian food requirements branch of the food distribution administration at the Department of Agriculture in Washington D C, according to the *Journal-Lancet*. —Dr Henry Hutchinson Moose Lake assistant superintendent of Moose Lake State Hospital for the last five years has been appointed superintendent of the Hastings State Hospital Hastings.

NEW JERSEY

Bank Names Room in Honor of Physician—On May 25 The McBride Room in the Paterson Savings Institution was dedicated to Dr Andrew F McBride Sr chairman of the board of the bank. A feature of the occasion was the unveiling of an oil portrait of Dr McBride painted by James McBev. The new room not only is to be used by the personnel of the bank but will be available for public meetings of a civic cultural and patriotic nature according to the state medical journal. Among the speakers were the Rt Rev Mgr L A McBride brother of the physician, C Kenneth Fuller president of the bank, Dr Francis H Todd and Dr McBride. The physician is a past president of the Passaic County Medical Society, trustee of the Medical Society of New Jersey and in 1929 was president. He is also a member of the House of Delegates of the American Medical Association.

NEW YORK

Symposium on Wartime Nutrition—A group of health agencies sponsored a symposium on wartime nutrition at the Hotel Statler Buffalo June 24. Among the speakers were Drs Edgar C Beck Buffalo on The Normal Diet, Donovan J McCune New York The Basic Principles of Diet in the Treatment of Disease, Fred L Adair Washington D C The Use and Abuse of Vitamins in Therapy, William W Bauer director Bureau of Health Education American Medical Association Chicago Food and the Future.

New York City

Exhibit on Occupational Therapy—Occupational Therapy Its Function and Purpose is the theme of an exhibit at the Museum of Modern Art. The exhibition which opened on June 1 and will continue throughout the summer is sponsored by the American Occupational Therapy Association.

Dr Rhoads on Leave as Director of Memorial Hospital—Dr Cornelius P Rhoads director of Memorial Hospital for the Treatment of Cancer and Allied Diseases has been given a leave of absence to become chief of the Medical Division of the Chemical Warfare Service of the U S Army. Science reports. He will have the rank of colonel. Dr Fred W Stewart pathologist at the hospital has been named acting director and Dr Howard C Taylor Jr assistant.

Workmen's Compensation Investigation—Dr Theodore R Freedman Brooklyn has been restrained from treating workmen's compensation claimants pending the outcome of an indictment for larceny in connection with padding bills for treating these patients according to the New York *Times*. The action was taken after the physician had admitted he padded his bills, bribed state employees, exaggerated treatment and participated in the splitting or refunding of fees, also solicitation of business and corrupt practices with a licensed representative to whom he paid substantial kickbacks. Dr Freedman was awaiting trial in General Sessions on the larceny indictment the *Times* stated.

OKLAHOMA

State Medical Election—Dr Charles R Rountree Oklahoma City was chosen president-elect of the Oklahoma State Medical Association at its annual meeting May 11 and Dr James Stevenson Tulsa was inducted into the presidency. Dr James G Edwards Okmulgee, is vice president and Dr Lewis J Moorman Oklahoma City secretary. The next annual session will be held at Tulsa in 1944.

Dr John Cowan Named Venereal Disease Officer—Dr John A Cowan health officer of Sioux City Iowa has been appointed venereal disease officer for the Oklahoma State Department of Public Health succeeding Eugene A Gillis, passed assistant surgeon U S Public Health Service, who has held the position for four years on loan from the public health service. Dr Gillis is being transferred to Austin, Texas.

OREGON

Changes in Bureau of Industrial Health—Thomas F Mancuso assistant surgeon U S Public Health Service reserve who has been on assignment to the Michigan Department of Health has been named to succeed Harold T Castberg passed assistant surgeon U S Public Health Service who has been organizing the Oregon state industrial hygiene division. Dr Castberg has been assigned to the California Bureau of Industrial Health, of which he formerly served as acting chief.

SOUTH CAROLINA

Special Society Election—Dr William P Patterson Pryor Hospital Chester was chosen president-elect of the South Carolina Hospital Association at its annual meeting in Columbia on May 26. Other officers include Mr Jacques B Norman Spartanburg president, Miss Katharine O Altman R N Lancaster, Mrs Lula B Lamar R N Aiken and Mr George W Holman Rock Hill vice presidents and Mr R L Dougherty Columbia secretary-treasurer.

Committee to Investigate Medical Education and Services—Gov Olin D Johnston Columbia recently appointed Senator O T Wallace Charleston to a seven man committee created by the general assembly to investigate medical education and medical services in South Carolina. Two other members of the committee which was given a thousand dollars for expenses were named by the senate two by the house of representatives and two by the president of the South Carolina Medical Association. The committee has been directed to submit its report on or before January 1.

UTAH

Activities at University of Utah—Recent appointments at the University of Utah School of Medicine Salt Lake City include that of Dr Fuller B Bailey as acting professor of internal medicine. The executive committee of the recently appointed school staff now include Dr Bailey and Drs Philip B Price professor of surgery, A Louis Dippel professor of obstetrics and gynecology and John A Anderson professor of pediatrics. According to an announcement the medical school which was recently augmented to include four years instruction is now operating in a satisfactory manner. The main portion of the teaching in the clinical years is being done at the Salt Lake County General Hospital which before the teaching program began had about 250 beds. Additional space has now been taken in the infirmary building and the capacity will soon be increased an additional 100 beds. The pediatrics department will be moved from the present hospital and will occupy the first floor of the infirmary building providing a pediatric division of about 60 beds. Medicine will be moved to the second and third floors of the west wing of the infirmary providing for about 80 straight medical beds and leaving room for considerable expansion for surgery and gynecology in the present hospital building. A clinical amphitheater is about to be constructed and money has been approved to enlarge materially the laboratories and the surgical operating rooms and accessory rooms. Quarters have been provided for student laboratories and for a students lounge or rest room where they may study. In addition an adequate library and reading room will be installed in the hospital. An admission center with a casualty ward is being developed on the first floor wing of the hospital near the ambulance entrance making the admitting station more convenient than has heretofore been the case. The administrative portion of the hospital will be placed entirely in the center section of the main floor. A new isolation hospital is to be constructed with federal funds. Clinical pathologic conferences are held once a week for one hour on Friday afternoons and in addition once every two weeks a clinical pathologic conference is held for physicians of the community at which they are requested to present pathologic material and case histories for discussion. The fourth year which is not yet operative contemplates eighteen weeks of election. There is a department of industrial health. Teaching and tropical medicine will be available and the medical school has been approved for medical teaching under the specialized training programs of the army and navy.

VIRGINIA

Physician Fined for Income Tax Evasion—*Southern Medicine and Surgery* reports that Dr. James W. Tipton of Danville was fined \$20,000 by Judge Robert N. Pollard in Federal District Court, May 27, on six charges of income tax evasion. The physician was said to have pleaded nolo contendere to an indictment listing six charges of evading income taxes from 1936 through 1941, during which period Lester L. Lurr, special agent of the internal revenue department, testified he filed improper returns and paid \$1,373.92 when his total liability to the government was \$22,490.99. The medical journal reported that the defense presented no oral argument but requested that a prison sentence be not imposed. Maximum penalty for each of the six counts is \$10,000 fine and five years' imprisonment. Under the law, in addition to the \$20,000 fine, the physician must pay back income taxes amounting to \$27,373.15, plus penalty and interest, which will bring his tax liability to well over \$52,000, it was stated.

Past Presidents' Night—The Richmond Academy of Medicine designated its meeting of May 25 as past presidents' night. There have been fifty-four presidents of the academy since 1890. Dr. Arthur S. Brinkley is now president and other living past presidents, all of Richmond, are:

Dr. Stuart McGuire	Dr. Wendell B. Blanton
Dr. William I. Mercer	Dr. William H. Higgins
Dr. Ramon D. Garcm	Dr. James Morrison Hutchison
Dr. Charles R. Robins	Dr. Robert Imley Gayle Jr.
Dr. John Shelton Horsley	Dr. Carrington Williams
Dr. Alexander G. Brown Jr.	Dr. Frederick P. Fletcher
Dr. William Lowndes Peple	Dr. Rosner W. Miller
Dr. Thomas W. Murrell	Dr. Marvin Pierce Rucker
Dr. James K. Hall	Dr. Austin I. Dodson
Dr. Frederick M. Hodges	Dr. John Powell Williams
Dr. Claude C. Coleman	Dr. William Branch Porter
Dr. Stuart N. Michans	Dr. Beverly R. Tucker
Dr. James H. Smith	

Five of this group were not present at the special meeting: Dr. McGuire, Dr. Blanton, Dr. Hutchison, Dr. Tucker and Dr. Williams, who is in North Africa.

WEST VIRGINIA

Committee to Study By-Laws—Dr. Robert J. Wilkinson, Huntington, president of the West Virginia State Medical Association, has appointed a special committee to submit a report to the council on the revision of the constitution and by-laws. The committee is composed of Drs. James Howard Anderson, Hemphill, chairman, Frank C. Hodges, Huntington, and James L. Wade, Parkersburg.

Honorary Life Members—At the recent meeting of the West Virginia State Medical Association the following physicians were made honorary life members: Drs. Wessie P. King and George Snyder, Weston, Albert L. Amick, Charleston, John H. Hansford, Pratt, William A. McMillan, Charleston, William C. Camp, Spencer, J. Riley McCollum, St. Marvs, Edwin W. Crooks, Roy Benson Miller, Lonzo O. Rose and Albert L. Wright, all of Parkersburg, Jesse S. Maloy, Shinnston, and Martin F. Wright, Burlington.

GENERAL

Bibliography on Blood and Plasma Storage and Transfusion—The General Electric Company, 5 Lawrence Street, Bloomfield, N. J., has made available a complete bibliography of articles and publications dealing with the storage and transfusion of blood and plasma. The company announces that it will mail copies of this material to any physician who is especially interested in the subject.

Specialty Board Examinations—The American Board of Internal Medicine will hold regional oral examinations in New Orleans, August 10-11. Oral examinations in the subspecialties will be included. Requests for admission should be filed with Dr. William A. Werrell, assistant secretary-treasurer, American Board of Internal Medicine, 1301 University Avenue, Madison, Wis.—The American Board of Otolaryngology will hold its next examination in Chicago, October 6-9, at the Palmer House and the Illinois Research Hospital. Dr. Dean M. Lierle, University Hospitals, Iowa City, is the secretary-treasurer of the board.

Grants for Infantile Paralysis Study—Twenty-eight grants totaling \$354,370 have been made by the National Foundation for Infantile Paralysis to universities, hospitals, laboratories and other organizations in eleven states to continue the fight against the disease. Sixteen grants, totaling \$216,020,

were made for virus and after-effects research. Four of these are on long-term projects being conducted at Yale University, New Haven, Conn., Johns Hopkins University, Baltimore, the University of Michigan, Ann Arbor and the University of Wisconsin, Madison. Twelve grants, totaling \$138,350, were made for various educational programs including the training of technicians in the Kenny method of treatment. Some of these grants include projects for educational work for physicians and the public. The sum of \$2,500 was appropriated for the preparation of a complete bibliography on poliomyelitis. The compilation is being done for the foundation with the aid of the library of the American Medical Association and the John Crerar Library, both in Chicago. The money will be disbursed in California, Connecticut, Georgia, Illinois, Iowa, Maryland, Massachusetts, Michigan, New York, Pennsylvania and Wisconsin.

Special Society Elections—Dr. Frank W. Konzelmann, Wilmington, Del., was chosen president-elect of the American Society of Clinical Pathologists at its annual meeting in Chicago in June and Dr. Walter S. Thomas, Rochester, N. Y., was inducted into the presidency. Dr. Josiah J. Moore, Chicago, is vice president. The Board of Registry of Medical Technologists consists of Drs. Lall G. Montgomery, Muncie, Ind., Israel Davidsohn, Chicago, and Ralph G. Stillman, New York. During the meeting the society presented the following awards. The Ward Burdick Award (*THE JOURNAL*, May 22, p. 245) was given to Dr. Max M. Strumia, Bryn Mawr, Pa., for his work on blood plasma, the gold medal for excellence in scientific exhibit to Dr. Davidsohn for his exhibit on blood groups, the silver medal for excellence in scientific exhibit to Drs. Samuel A. Goldberg, Newark, N. J., Solon N. Blackberg, Chicago, and Percy de Stanley, Union, N. J., for their exhibit on the pathology of arthritis, and the bronze medal for excellence in scientific exhibit to Dr. Sylvester E. Gould, Elouse, Mich., for his exhibit on pathology of trichinosis.—Dr. Herman C. Pitts, Providence, R. I., was recently reelected president of the American Society for the Control of Cancer at its annual meeting in New York. Other officers reelected include Dr. John J. Morton Jr., Rochester, N. Y., and Dr. Frank E. Adair, New York, vice presidents, Dr. Cornelius P. Rhoads, New York, secretary, and James H. Ripley, treasurer.—Dr. E. Arthur Whitney, Elwyn, Pa., was chosen president-elect of the American Association on Mental Deficiency at its annual meeting, May 16, and Dr. Charles Stanley Raymond, Wrentham, Mass., was installed as president. Dr. Neil A. Dayton, Mansfield Depot, Conn., is the secretary.

Wartime Trends in Tuberculosis—There is no evidence from insurance figures that the increased employment of women in industry since the outbreak of the war has adversely affected their tuberculosis death rate, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company. Longer hours of work, crowded living conditions in war production centers and curtailed food supplies have thus far not interrupted the longtime downward trend of the disease, it was stated. In 1942 the tuberculosis death rate among Metropolitan industrial policyholders was 5 per cent lower than the average for the prewar period 1939-1941. Moreover, during the first four months of the current year, a period of peak industrial activity, the mortality was 5.5 per cent less than for the similar period of 1942. It is an arresting fact that each month since Pearl Harbor, except one, has registered a lower death rate for tuberculosis than the corresponding month in the prewar period. The bulletin stated that for the general population complete data for 1942 are not yet available, but preliminary figures indicate a similar downward trend. Figures released by the insurance company indicate that white women experienced the largest relative decrease in mortality during 1942, slightly more than 10 per cent from the average rate during the 1939-1941 period. Their death rate from tuberculosis in 1942 was 23.1 per hundred thousand. White males showed a decline of under 2 per cent with a rate of 41.4 per hundred thousand. The bulletin states that at the time of the first world war the tuberculosis mortality among the policyholders was about five times the current figure. The mortality from tuberculosis in 1942 for Negroes had fallen 5 per cent for women and 7 per cent for men as compared with the prewar average. The improvement is gratifying since it has been achieved in the face of increased industrial employment among the Negroes but, on the other hand, the bulletin points out, one must remember the high standard of living that increased employment and income have brought to many of these people.

British Medical Association Representatives Reject Government Proposals for a State Medical Service for All

A representative committee was appointed by the British Medical Association to enter into noncommittal discussions with the minister of health on the Beveridge scheme for a complete state medical service for all persons. The committee was appointed at his request. Discussions have been proceeding for two months and the committee which undertook to report from time to time to the profession has presented its first report. The Ministry of Health put forward tentative proposals for a comprehensive medical service based on central and local administration and the employment of doctors as salaried officers, mainly whole time by a new type of local authority. The representative committee came to the conclusion that further discussion on the basis of the proposals made by the Ministry of Health would be unfruitful. It therefore met the minister of health and told him that though not empowered to commit the medical profession, it believed that the proposals would be contrary to the public interest and unacceptable to the great majority of the medical profession. It therefore asked for its withdrawal.

In reply the minister of health stated that the only government commitment on the subject of a comprehensive health service was that which was outlined by the government in the House of Commons. The government was not committed to any particular form of medical service. His proposals were put forward only as a basis of discussion and he agreed to a reexamination of the whole position. He would proceed to express his conclusions in a paper which would then be open for consideration by the public and the medical profession before final decision by Parliament. The representative committee of the British Medical Association accepted these assurances and decided to continue noncommittal discussions with the minister.

At a mass meeting of the Metropolitan Counties Branch of the British Medical Association the deputy secretary, Dr Charles Hill delivered an address which revealed the objections of the representative committee to the scheme. The minister of health proposed to set up at the center a medical service council three fourths of the members to be nominated by the profession and the remainder by the minister. Locally there would be a grouping of most local authorities for health purposes by means of joint boards. There might be medical membership of these boards but it would probably be small. General practice would be based on health centers where clinical work would be done. Believing that competition for patients under the roof of the center would be undesirable the minister proposed that in the main general practice should be on a salaried basis. Those now in general practice could enter the service as whole time or part time officers. In the latter case they could continue private practice among those who, though entitled to the state service preferred to consult a doctor privately. But new entrants would have no choice. After an initial period as house officer an entrant would receive \$2,000 a year for three years. Then he would normally become a principal at a salary of \$3,250 rising by annual increments of \$150 over eighteen years to \$6,000. Expenses including travel would be paid in addition.

Dr Hill asked: Why such hurry? Why was the government pressing forward with such energy one section of the Beveridge proposals? Was it anxious to do something and

found a profession of 50,000 men and women easy to handle? A free profession was to be transmuted into a branch of local government service. Whatever might be thought of the methods of remuneration as a profession they could not accept this. Some of them knew from their experience that the caliber of members of local authorities would not justify the handing over to them of personal domiciliary and other medical practice. The committee had suggested that the only effective way of dealing with the whole problem was to remove it from the ambit of the present discussions and to place it before a royal commission (a commission appointed by the government to investigate certain questions. It takes evidence on them and then formulates conclusions).

New Life Saving Devices at Sea Drinking Water from Sea Water

A satisfactory method of producing drinkable water from sea water has been the subject of experiment for some time. The Ministry of War announces that distillation has proved to be the best method and that all lifeboats and ocean going merchant ships are to be equipped with stills. Three types have been produced by the Department of Scientific and Industrial Research which has been making experiments on behalf of the Ministry of War Transport. One already in production produces half a gallon of fresh water per hour. Thus on a fourteen day voyage the still, working ten hours daily, would produce 70 gallons twice the amount necessary for a lifeboat intended for 40 persons. The still can be worked with either solid fuel or paraffin but it is intended to rely primarily on coal briquettes, which are readily stored in odd corners of the lifeboat supplemented by any wood or waste material in the boat or recovered from the sea. The other two types consume paraffin and are expected to have a higher output in relation to fuel consumption. Their development is continuing, with the intention of offering the shipping industry a choice.

The stills are also to be used for boiling water to make hot drinks, and their heated surfaces will dry wet clothes. The fresh water already carried in tanks in lifeboats will be maintained. In addition the ministry is producing a new type of device made of cotton fabric for catching rain. In a demonstration given on a ship on the Thames it was shown that the stills are simple to work. The ministry is also producing improved life saving waistcoats fitted with rope gear to facilitate rescue portable ladders to enable men in the water to climb into lifeboats new lifeboat ration biscuits with an increased fat content and side seat extensions to provide facilities for lying down.

Fitness Center for Miners

Since the outbreak of war much attention has been given to the treatment and the after-treatment of injuries which has become more specialized and is carried out at organized centers. The latest example is the opening at Gleneagles in Scotland of the fitness center for miners. It is an indication of the importance attached by the government to the waste of physique and the need for a scientific system of rehabilitation after injury or illness. The experiment is being watched not only by people interested in coal mining but by those concerned with the replacement in industry of men discharged from the forces. The problem of rehabilitation has been studied by the Department of Health for Scotland in conjunction with the Miners' Commission.

It has been shown that the average period of disability after fracture—which form a large part of the disabling injuries of miners—can be halved and the number permanently disabled reduced by methodical treatment. There was a gap to be filled between the time the patient leaves the hospital and when he is fit to return to work. The idea is to create the will to get

well and the desire to resume work. For this it has been found advisable to get rid of the atmosphere of the hospital ward. Hence there are no nurses in the rehabilitation center and no hours of idleness. The patients are examined carefully and graded according to the activity of which they are capable. Whatever grade they are allotted to they do a full day's work, their remedial exercises being adapted to their various needs. Into this treatment physical therapy, occupational therapy and physical and vocational training and massage enter. Entertainment is considered important and is provided by cinema and in other ways, including talent supplied from among the patients themselves. The average duration of the fitness treatment is about six weeks. Those who have passed through the center are loud in their praises of it.

AUSTRALIA

(From Our Regular Correspondent)

May 27, 1943

The Australian War Pharmacopeia

Although Australia today is reasonably well supplied with most essential drugs for medical purposes, it is of the utmost importance that every effort should be made to conserve present supplies. This has been partially achieved by widespread appeals to medical practitioners to avoid prescribing medicines unless medicinal treatment is especially indicated, and emphasis has been placed on the necessity for introducing uniformity into prescription writing.

In pursuance of these principles the Medical Equipment Control Committee has recently published an Australian War Pharmacopeia which, it is hoped, will supersede all other standing pharmacopeias throughout the commonwealth during the war period. The selection of medicines included in this work covers most ordinary therapeutic requirements, but nonessential drugs have been eliminated and those which are in short supply or are more urgently needed in different phases of the national war effort have been limited as far as possible or been replaced by alternative drugs. The pharmacopeia has been distributed throughout the commonwealth, and the cooperation of Australian pharmacists has been sought. It has already been adopted by several large hospitals in the various states. The voluntary acceptance of this work by the medical profession will constitute an important contribution to the conservation of drugs in wartime Australia.

The Tuberculosis Problem in Australia

It is not known whether there has been any increase in tuberculosis in Australia during the present war period. Medical practitioners are not forced to notify cases unless the patient reacts to the Mantoux test and is found to have visible tubercle bacilli in the sputum. The medical profession of this country has for years emphasized the importance of early diagnosis and treatment of tuberculosis and the need for financial provision for the immediate dependents of the tuberculous and for a commonwealth organized rehabilitation project. The adoption by the commonwealth early in the war of routine x-ray examination of entrants for the Australian Imperial Forces and Royal Australian Air Force has constituted a forward step toward the achievement of these measures. But at present there are only a few centers where microradiography for the diagnosis of tuberculosis is undertaken for civilians, and no systematic survey has been attempted.

The economic aspect of the problem has been somewhat alleviated under wartime conditions. In peacetime a man was dependent on his employer and often dared not say that he was tuberculous. If he was forced to enter a sanatorium there was no adequate financial support provided for his family, and there were so many men available that he experienced great difficulty in finding work on reentering civil life. Now the manpower

authorities deal with such cases, and they are placed back in gainful occupations. The village settlement scheme for rehabilitation, which has been successful in other countries, has not been tried out in Australia.

Agar Production in Australia and New Zealand

During the past two years the possibilities of agar agar production in Australia and New Zealand have been explored. Here in Australia agar is being produced from a red seaweed, *Gracilaria confervoides*, which is easily harvested and is available in quantity. The results so far achieved have been promising. The agar produced has a higher ash and lower nitrogen content than the Japanese variety and a somewhat lower gelling power but has provided suitable mediums for the growth of most bacteria.

In New Zealand two species of Gelidiaceae offer commercial possibilities owing to their relative abundance, easy identification and good yield. Last year the Council for Scientific and Industrial Research carried out small scale experiments with one of these, *Pterocladia lucida*, with satisfactory results. Further investigations are now in progress.

Pyoderma Ulcerosum Tropicalum—A New Clinical Entity

Under the term pyoderma ulcerosum tropicalum Capt O. Alpins (A. A. M. C.) describes an infectious skin disease which incapacitated a large number of men serving in certain tropical areas in the Northern Territory of Australia. He considers it to be a new clinical entity. The condition is epidemic in the wet season (December to May) when the vegetation is moist and flourishing, the incidence falling considerably with the onset of drier conditions. Regarded as predisposing factors are lowered resistance from previous illness, malnutrition (especially lack of vitamins), fatigue and absence of suitable protective clothing. The infection can generally be traced to scratches from vegetation or barbed wire, and probably to the scratching of mosquito bite and "prickly heat." The incubation period varies from six to twelve hours. The lesions are mainly situated on the extensor surfaces, such as the knees, the upper parts of the legs, the forearms and the backs of the hands. They are characterized by the development of primary discrete vesicles with associated areas of inflammation. The vesicles have a whitish appearance but contain straw colored fluid. Soon they break, forming a superficial circular ulcer the edges of which are thickened in varying degrees and surrounded by a painful cellulitis. When left alone the ulcer becomes covered by a firm yellowish crust, under which the ulcer deepens and extends, until eventually the crust breaks, exposing a deep ulcer, varying from 1 to several inches in diameter. The condition was experimentally transmitted by autoinoculation, by the inoculation of vesicle and ulcer material intradermally and by the swabbing of material into an abrasion on 5 subjects who were free from any previous skin complaint. In early cases (one week) a pure growth of group A hemolytic streptococci was obtained and in later cases a mixed growth of group A hemolytic streptococci and *Staphylococcus aureus*. Swabbings from the experimental inoculations yielded a hemolytic streptococcus with a few columns of *Staphylococcus aureus*. Alpins concludes that the organism responsible is a hemolytic streptococcus, a *Staphylococcus aureus* infection being superimposed.

A Drug Plant Survey

The Council for Scientific and Industrial Research is at present carrying out an extensive survey in coastal Queensland areas for the purpose of locating indigenous or naturalized plants which may be sources of certain drugs such as caffeine, ephedrine, cocaine and quinine substitute, and of substances such as derris. Analyses of the material collected are being carried out by the Department of Pharmacy and Physiology of the Universities of Sydney and Melbourne respectively.

Deaths

Karl Landsteiner, New York renowned for his research on human blood groups and the chemistry of immunity Nobel Prize winner in 1930 died in the Hospital of the Rockefeller Institute for Medical Research, New York, June 26, of heart disease aged 75.

Dr Landsteiner was born in Vienna Austria June 14, 1868 and graduated in medicine at the University of Vienna in 1891. He studied chemistry for a while with Emil Fischer but soon devoted himself to pathologic research and teaching. In 1898 he was appointed assistant in the Pathologic-Anatomic Institute of the University of Vienna. In 1908 he became professor at the Wilhelmspital in Vienna, serving there in 1909 as lecturer on pathologic anatomy and in 1911 as professor extraordinary. The disturbances in Vienna after World War I led Dr Landsteiner to go to the Netherlands, where he worked at the R. K. Ziekenhuis at The Hague as professor until 1922 when he was invited to join the staff of the Rockefeller Institute for Medical Research, New York. In 1939 he was one of a group who were retired under a mandatory rule. However he diligently continued his work in the laboratory made available by the institute, and it was here that he became ill Thursday June 24.

In 1930 Dr Landsteiner was awarded the Nobel Prize in medicine for his discovery of isoagglutination and the human blood groups. This discovery has had a profound influence on therapeutic blood transfusion by obviating its hazards. It also made it possible to determine parentage in certain cases and to trace the source of blood stains. His first statement about human isoagglutination appeared in a footnote to an article in 1900 about the agglutinating and other actions of blood serum and lymph. He also demonstrated the mechanism of paroxysmal hemoglobinuria in which blood is broken down when a foot or an arm is chilled. With Popper Dr Landsteiner in 1909 first transmitted infantile paralysis to the monkey; this was followed by the experimental work of others which brought to light all we now know of the nature of the causative agent of this disease. Another outstanding achievement was his study through many years of fundamental problems in immunity particularly the chemistry of the specificity of immune reactions. A revision of his book *The Specificity of Serological Reactions* a classic in its field was published not long ago. He also introduced a method of darkfield demonstration of the micro-organism of syphilis. Only recently he showed that drug allergy partakes of the nature of typical immune reactions. He also took an active part in the work that led to the discovery of the Rh factor which has been found to play an essential role in erythroblastosis fetalis.

Besides the Nobel Prize Dr Landsteiner received many honors notably the annual prize of the Hans Aronson Foundation of Berlin in 1926 the Paul Ehrlich gold medal in 1930 the gold medal of the Dutch Red Cross Society in 1933 and the Cameron Prize of the University of Edinburgh in 1938. Honorary degrees were conferred on him by the University of Chicago Cambridge University Harvard University and the University of Brussels. He was made a Chevalier of the French Legion of Honor. He was a member of or held honorary fellowship in the National Academy of Sciences the American Philosophical Society the Royal Swedish Academy of Science the Danish Academy of Science Deutsche Akademie der Naturforscher the Swedish Medical Society the Harvard Society the Royal Society of London Societe Belge de Biologie Pathological Society of Great Britain and Ireland Vienna Medical Society New York Academy of Medicine American Society of Naturalists Royal Society of Medicine Pathological Society of Philadelphia Reale Accademia delle Scienze (Italy) and the Medical Chirurgical Society of Edinburgh. In 1929 he was president of the American Association of Immunologists.

Dr Landsteiner married Helene Wlasto in 1916. Both became American citizens and their son Dr Ernst Landsteiner is a graduate of the Harvard Medical School and now a surgical resident at the Peter Bent Brigham Hospital in Boston.

Dr Landsteiner's death closes a brilliant career. He was a shy and modest man. The worldwide acclaim and recognition were deserving tributes to his patient devotion to pure research. The practical application of his results he left to others.

Harry Gaylord Dorman of Cambridge Mass. Columbia University College of Physicians and Surgeons New York 1900 an Associate Fellow of the American Medical Association specialist certified by the American Board of Obstetrics and Gynecology Inc. fellow of the American College of Surgeons formerly professor of pediatrics professor of obstetrics and gynecology and dean at the American University of Beirut

School of Medicine, Syria, for many years pediatrician gynecologist and obstetrician to the American University Hospital at Beirut attending surgeon to the Johanner Hospital, Beirut, from 1916 to 1918 and consulting surgeon to the Turkish Military Hospital from 1916 to 1918, head of the Red Cross Relief Expedition to Adana Turkey, in 1908 author of a textbook of General Pathology 1906 aged 67, died April 22 of coronary thrombosis.

Emory John Brady of Colorado Springs Colo. Detroit College of Medicine, 1901, past president of the El Paso County Medical Society member of the American Psychiatric Association and the Central Neuropsychiatric Association past vice president of the American Association of Private Psychiatric Hospitals served for two terms as a member of the House of Representatives and one term in the Senate at one time on the staffs of the Michigan Asylum for the Insane Kalamazoo Mich. Woodcroft Hospital, Pueblo assistant superintendent of the Newberry (Mich.) State Hospital and superintendent of the Myron Stratton Home owner and superintendent of the Colorado Springs Psychopathic Hospital a director of the Colorado Springs National Bank a member and formerly director of the Colorado Springs Rotary Club aged 68, died April 19 of bronchopneumonia.

Montague Sydney Woolf of San Francisco, L.R.C.P. of London and M.R.C.S. of England 1914 associate clinical professor of surgery at the University of California Medical School specialist certified by the American Board of Surgery member of the American Proctologic Society fellow of the American College of Surgeons visiting surgeon to the University of California Hospital and Laguna Honda Home on the staffs of the Childrens and St. Mary's hospitals served in the Royal Army Medical Corps during World War I author of *Principles of Surgery for Nurses* consulting surgeon to the Southern Pacific Railroad aged 59, died April 20 of bacterial endocarditis.

Julius Napoleon Hill, Murphy N.C. University of Louisville (Ky.) Medical Department 1909 member of the Medical Society of the State of North Carolina president of the Cherokee County Medical Society for several terms served as a medical officer in the U.S. Army during World War I for many years Cherokee County physician a trustee of the Murphy city schools and the Western North Carolina Teachers College Cullowhee on the courtesy staff of the Petrie Hospital aged 57 died April 27 in the Veterans Administration Facility Atlanta of chronic myocarditis and arterial hypertension.

Edward Henry French, Quincy Mass. Dartmouth Medical School Hanover N.H. 1882 member of the New Hampshire Medical Society and the American Psychiatric Association, assistant superintendent of the New Hampshire State Hospital Concord from 1883 to 1896 superintendent of the Medfield State Hospital from 1896 to 1917 in 1935 was presented with a gold medal by the New Hampshire Medical Society in recognition of his fifty years of membership in the society aged 86 died May 4 in the Baker Memorial Massachusetts General Hospital Boston of coronary thrombosis.

Harry Lowenbush Sr. of Philadelphia Medico-Chirurgical College of Philadelphia 1901 specialist certified by the American Board of Pediatrics Inc. veteran of the Spanish-American War served as a captain in the medical corps of the U.S. Army during World War I formerly lecturer in pediatrics at his alma mater, chief in pediatrics at Mount Sinai and Philadelphia General hospitals consulting chief to the Jewish Hospital formerly medical director of the Northeastern Hebrew Orphans Home aged 64, died April 8 of heart disease.

Dewitt Peake Bailey, Binghamton N.Y. University of the City of New York Medical Department New York 1889 aged 76 died April 30 in the Binghamton City Hospital of pneumonia.

Harry William Bauer Palmyra N.J. Medico-Chirurgical College of Philadelphia 1909 member of the Medical Society of New Jersey aged 58 died April 19 in the Cooper Hospital Camden of cerebral hemorrhage.

Cesar George Caben Los Angeles University of Southern California College of Medicine Los Angeles 1909 member of the California Medical Association chief consulting surgeon of the French Hospital served as a major in the French army during World War I a member of the French Legion of Honor aged 58 died April 29 of heart disease.

Roy Munro Collie of Schenectady N.Y. Albany (N.Y.) Medical College 1906 a member of the board of trustees of the Schenectady Savings Bank aged 59 on the staff of the Ellis Hospital where he died April 24 of hypertensive heart disease.

Games Stanley Dobbins Jr, Cumberland, Ky., University of Louisville School of Medicine, 1938, member of the Kentucky State Medical Association, examining physician for the Selective Service System, member of the staff of the Lynch (Ky.) Hospital, aged 32, died April 30.

Raymond Goulden Edmians, Troy, N. Y., Albany (N. Y.) Medical College, 1898, formerly coroner of Rensselaer County and deputy health commissioner, medical examiner for the Metropolitan Life Insurance Company for many years and served as chief examiner for several other insurance companies, aged 71, on the staff of the Troy Hospital, where he died April 22 of heart disease.

Clarence P. Gammon, Tacoma, Wash., Rush Medical College, Chicago, 1899, member of the Washington State Medical Association, formerly a member of the state board of health, veteran of the Spanish American War and World War I, member of the staff of St. Joseph's Hospital, served as surgeon for the Union Pacific Railroad for many years, aged 70, died April 24, of coronary disease.

William Vincent Guttery ♂ Middletown, Ill., St. Louis Medical College, 1881, an Affiliate Fellow of the American Medical Association, aged 92, died April 20, of chronic myocarditis.

John Frank Hogan, Birmingham, Ala., Birmingham Medical College, 1903, member of the Medical Association of the State of Alabama, formerly on the staff of the Davis Infirmary, aged 60, died April 30, of traumatic abscess of liver.

Willard Carlisle Johnson ♂ Detroit, Harvard Medical School, Boston, 1927, member of the Medical Society of the State of New York, aged 47, died April 23, of coronary occlusion.

Robert Rives Jones, Winston-Salem, N. C., Medical College of Virginia, Richmond, 1923, member of the Medical Society of the State of North Carolina, formerly a member of the city health department, aged 45, served on the staffs of the Kate Bitting Reynolds Memorial Hospital, North Carolina Baptist Hospital and the City Memorial Hospital, where he died April 13, of cerebral hemorrhage.

George Warton Kaan, Sharon, Mass., Harvard Medical School, Boston, 1890, member of the Massachusetts Medical Society, served as treasurer of the Norfolk District Medical Society, professor of clinical gynecology emeritus at the Tufts College Medical School, Boston, formerly on the staffs of the Free Hospital for Women, Adams Nervine Asylum and the New England Deaconess Hospital, Boston, a founder and for many years on the staff of the Boston Dispensary for Women, aged 88, died April 14, in Stoughton of prostatic hypertrophy.

Harry Delman Kelly, Council Bluffs, Iowa, John A. Creighton Medical College, Omaha, 1903, member of the Iowa State Medical Society, member of the staff of the Mercy Hospital, aged 60, died April 20, in the Doctors' Hospital, Omaha, of bronchopneumonia.

George W. Kennedy, Beulaville, N. C., University College of Medicine, Richmond, 1898, for many years a member of the school board, aged 64, died April 7, of angina pectoris.

John W. Laird, Mount Pleasant, Iowa, Hahnemann Medical College and Hospital, Chicago, 1900, member of the Iowa State Medical Society, past president of the Henry County Medical Society, served during World War I, health officer of Mount Pleasant, aged 71, died April 26, of coronary thrombosis.

Erford Haskell Lamb, Cornelia, Ga., Atlanta College of Physicians and Surgeons, 1911, member of the Medical Association of Georgia, aged 65, died April 23, of influenza and myocarditis.

Smith J. Mann, Livermore, Calif., Willamette University Medical Department, Salem, Ore., 1907, member of the American College of Chest Physicians, served during World War I, manager of the Veterans Administration Facility, aged 60, died April 27, of coronary thrombosis.

Charles Lewis Marks, Montgomery, Ala., University of Virginia Department of Medicine, Charlottesville, 1904, member of the Medical Association of the State of Alabama, aged 61, died April 30, of heart disease.

Thomas Alexander Norment, Lumberton, N. C., North Carolina Medical College, Davidson, 1894, aged 72, died April 10, in the Thompson Memorial Hospital of arteriosclerosis.

Paul Wilmer Oakes, Cleveland, Western Reserve University School of Medicine, Cleveland, 1938, member of the Ohio State Medical Association, examining physician for draft

board number 3, served on the staffs of the Lakewood (Ohio) Hospital, Evangelical Deaconess Hospital and the Fairview Park Hospital, where he died April 21, of nephritis, aged 30.

Samuel Orr Price, Taylor, Miss., Memphis (Tenn.) Hospital Medical College, 1912, member of the Mississippi State Medical Association, aged 59, died April 15, of heart disease.

Herman F. Prill, Augusta, Wis., Milwaukee Medical College, 1902, member of the State Medical Society of Wisconsin, aged 68, died April 11, in the Luther Hospital, Eau Claire, of arteriosclerotic heart disease.

John Joseph Randall ♂ Wynantskill, N. Y., Albany (N. Y.) Medical College, 1917, member of the American College of Chest Physicians, served as a captain in the medical corps of the U. S. Army during World War I, medical director and superintendent of the Pawling Sanatorium, formerly medical director of the Sunny Acres, Cleveland Tuberculosis Sanatorium, Warrensville, Ohio, on the consulting staff of the Sumner Hospital and medical director of the chest clinic, Troy, aged 51, died April 29, of carcinoma.

Adolph Reich ♂ New York, University of the City of New York Medical Department, New York, 1891, formerly clinical professor of gynecology at the New York Polyclinic Medical School and Hospital, aged 78, died April 27, of lymphosarcoma.

Robert Macfeely Shea, Denver, University of Colorado School of Medicine, Denver, 1913, member of the Colorado State Medical Society, fellow of the American College of Surgeons, a lieutenant in the U. S. Navy during World War I, for many years district surgeon for the Union Pacific Railroad, member of the staffs of St. Luke's, Children's, St. Anthony's, St. Joseph's and Presbyterian hospitals, medical director of the Mercy Hospital, where he died March 21, of myocarditis, aged 60.

Laban Aaron Steeves ♂ Salem, Ore., University of Oregon Medical School, Portland, 1921, served in the medical corps of the U. S. Navy during World War I, aged 49, died March 30, of heart disease and hypertension.

George Washington Thume, Lincoln, Neb., Kansas City (Mo.) Medical College, 1898, served as a first lieutenant in the medical corps of the U. S. Army during World War I, aged 66, died April 10, of thyroid disease, diabetes mellitus and heart disease.

Charles C. Vinsant ♂ Maryville, Tenn., University of Tennessee Medical Department, Nashville, 1907, on the staff of the Fort Craig Hospital, aged 66, died April 22, of hypernephroma of the left kidney.

DeFriste Vogt, Cleveland, Hospital College of Medicine, Louisville, Ky., 1884, aged 80, died April 26, of heart disease.

John Leaman Winters, Blue Ball, Pa., Jefferson Medical College of Philadelphia, 1890, member of the Medical Society of the State of Pennsylvania, aged 74, died April 14, of arteriosclerosis.

DIED IN MILITARY SERVICE

Samuel Albert Barkoff, New Orleans, Louisiana State University School of Medicine, New Orleans, 1938, member of the Louisiana State Medical Society, began active duty as a first lieutenant in the medical reserve corps of the U. S. Army in June 1941 and later became a captain, aged 28, died April 17, in Tampa, Fla., of injuries received in an airplane accident.

Morris Lawrence Dressler, Belmont, Mass., Tufts College Medical School, Boston, 1921, member of the Massachusetts Medical Society, formerly served as city physician of Cambridge and as trustee of the Cambridge City Hospital, served during World War I and as a major in the National Guard, major in the medical corps, Army of the United States, stationed at Fort Dix, N. J., where he died May 6, of acute gangrenous cholecystitis, aged 44.

Frank Woodward Quin ♂ Surgeon, Lieutenant Commander, U. S. Navy, retired, Little Rock, Ark., Medical Department of Tulane University of Louisiana, New Orleans, 1911, entered the medical corps of the U. S. Navy in 1920 and retired in 1940, served during World War I, called back to active duty in March 1941, attached to the U. S. Marine Corps Receiving Station, aged 64, died March 21, in St. Vincent's Infirmary of cerebral hemorrhage and hypertensive heart disease.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Ace High Effervescent Preparation—Premium Color Work, New York and The Pepe Maisano Company, New Haven, Conn. Shipped Aug. 30, 1940. Composition not definitely reported but mention was made of an added poisonous or deleterious substance (borax). Use of product not stated. Adulterated because of presence of borax which was declared to be unsafe within the meaning of the law. Misbranded because listing of citric acid was false and misleading, since this was not one of the ingredients. Further misbranded because label did not bear the common or usual name of each of the actual ingredients.—[F N J F D C 2550 July 1942]

Apex Special Hair Pomade and Apex Pomenta—Apex News and Hair Company, Inc., Atlantic City, N. J. Shipped July 1, 1940. Composition: "Pomade" consisted of petrolatum with a small proportion of coal tar; composition of Apex Pomenta not reported. Both products misbranded because their containers were so made, formed or filled as to be misleading. The Pomade was misbranded further in the false representations that it would be effective for stubborn cases of dandruff, thin and falling hair and would be excellent for thin temples. Pomade was misbranded also because label did not list common or usual names of active ingredient.—[D D N J F D C 326 September 1942]

Chase Formula—Chase Laboratory, Detroit. Shipped Oct. 15, 1940. Composition: essentially a fatty oil (about 16 per cent) oleic acid (about 5 per cent) mineral oil (about 2 per cent) alcohol (by volume 17.3 per cent) and a small amount of triethanolamine with water. Misbranded because falsely represented as an effective treatment for athlete's foot, lumbago, poison ivy, body lice, many types of eczema and skin disorders caused by external infections, itching bites and shingles. Further misbranded because active ingredients were not conspicuously listed on the label and quantity or proportion of alcohol present was not correctly declared. Since the statement "denatured alcohol 25%" was incorrect.—[D D N J F D C 322 September 1942]

Common Sense Liniment—T. H. Jackson and Company, Quincy, Ill. Shipped Aug. 8, 1940. Composition: essentially linseed oil, pine oil, guaiacal, paraffin oil and a small amount of ammonia. Declared misbranded because label falsely represented that the product would be an effective treatment for ailments on man requiring an external application; that it possessed healing and relieving properties and was efficacious in treating muscular rheumatism, sciatic rheumatism, nervous headache, lame back, ear disorders, old corns, cuts, sores and some other conditions.—[D D N J F D C 325 September 1942]

Dr. Seifert's Glucoemine—Glucoemine Company of America, Richmond Hill, N. Y. Shipped between Jan. 20 and 30, 1941. Composition: essentially powdered plant tissues including potato starch. Adulterated because its strength differed from and its purity or quality fell below that which it purported to be in the labeling, namely, plant insulin substances, vegetable insulin. Glucoemines are extracted by a special process. The resulting preparation is free from carbohydrates. Misbranded because falsely represented to be a plant insulin which would be an effective treatment for diabetes by mouth, to be positively unsurpassed and to help stimulate the pancreas gland to produce insulin of its own. Further misbranded because label failed to give the common or usual name of each of the active ingredients.—[D D N J F D C 321 September 1942]

Kresto—Bestov Products, Inc., Long Island City, N. Y. Shipped Dec. 3, 1940. Composition: a mixture of sugar, cocoa malt and possibly a small amount of skimmed milk. Misbranded because of false label statements: "Health Energy." An extract of the most nutritive foods of nature. It is very rich in vitamins. Kresto aids the digestion of other foods and is a food prepared especially for nourishing the organism with the minimum of digestive effort. Kresto contains in correct proportion all the substances necessary for strengthening the brain, nourishing the bones, increasing the red corpuscles in the blood, building up the tissues, creating strong muscles and normal flesh. Alimentary value 43 calories to each teaspoonful. It

contains carbohydrates, protein, fats and mineral substances. Further misbranded because label failed to give the common or usual name of each ingredient.—[F N J F D C 2547 July 1942]

Leucorrhea Special No. 9—C. F. Breitenbach (Mucine Company) Chicago. Shipped between Jan. 22 and Nov. 11, 1940. Composition: quinine sulfate (0.64 per cent), boric acid (19.95 per cent) and thymol the whole incorporated in petrolatum. Adulterated because not of the strength and quality indicated and misbranded because of misrepresentation that the nostrum was good for leucorrhea and because labeling did not bear adequate directions for use. Further misbranded because label failed to bear name and place of business of manufacturer, packer or distributor since designation "Ainsworth Specialty Co., Kansas City, Mo." did not make clear this concern's connection with the product and because label did not give the common or usual name of each active ingredient or the quantity of the contents. Also misbranded because label failed to bear adequate directions for use.—[D D N J F D C 456 September 1942]

McClintock's Formula for Diabetes—Robert McClintock, Ann Arbor, Mich. Shipped between March 21 and May 24, 1940. Composition: essentially sulfuric acid, alcohol (75.05 per cent by volume) and water flavored with cinnamon oil. Misbranded because falsely represented as an efficacious treatment for diabetes and because of label claim "Reg. with U. S. Food and Drug Administration" since it was not so registered.—[D D N J F D C 320 September 1942] This product was one of the subjects of the Post Office fraud order issued July 14, 1938, debaring McClintock's quackish business from the mails, the details of which appeared in this department of THE JOURNAL Dec. 24, 1938, page 2409.

Pick Me Up Bath and Hangover Bath—Vandora Ltd., New York. Shipped between Feb. 7 and Dec. 21, 1940. Composition: Pick Me Up Bath—essentially ammonia (16.5 per cent by weight), alcohol (36 per cent by volume), water and green coloring matter. Hangover Bath—same composition except that the ammonia was 15.7 per cent by weight and the alcohol 40 per cent by volume. Misbranded because names of treatments gave false impression and also because labels did not bear common or usual names of active ingredients or declare quantity or proportion of alcohol present.—[D D N J F D C 328 September 1942]

Prevent All—C. F. Breitenbach (Mucine Company) Chicago. Shipped between Jan. 22 and Nov. 11, 1942. Composition: essentially 4.4 per cent of calomel and 9.3 per cent of zinc oxide, the mixture incorporated in wool wax (lanum). Adulterated because its strength differed from and its quality fell below that which it was represented to possess. Misbranded because composition claim on label "Lanum base 67%" "Calomel 33%" was false and misleading as were the representations that this was a combination to prevent all sexual diseases in the male, Gonorrhea, chancres (syphilis), destroys micro-organisms and prevents incubation, endorsed and recommended by leading physicians. Further misbranded because label failed to bear name and place of business of manufacturer, packer or distributor since designation "Ainsworth Specialty Co., Kansas City, Mo." did not make clear this concern's connection with the product and because label did not give the common or usual name of each active ingredient or its quantity.—[D D N J F D C 456 September 1942]

Savol and Savol Cream—Savol Chemical Company, Mercer, Pa. Shipped between Sept. 3 and Oct. 30, 1940. Composition: Savol—essentially creosols, alkali soaps and a small amount of phenol in water. Savol Cream—essentially zinc oxide, barium sulfate, petrolatum and perfume. Bacteriologic examination showed that Savol Cream was not antiseptic. Savol misbranded because falsely represented to be an effective treatment for nasal catarrh, hay fever, bites of animals and irritation of the throat and a preventive of infected sores, abscesses, boils, felon and all complications due to infections. Savol Cream misbranded because falsely labeled to be efficacious as an antiseptic for cuts, bites of animals, all forms of hemorrhoids, skin disorders in general, sore throat, croup, enlarged glands, boils, felon, ulcers and eczema or as an after-treatment of boils, felon, carbuncles and erysipela. Both products misbranded because labels failed to list common or usual names of active ingredients or to give accurate statements of the quantity of content.—[D D N J F D C 323 September 1942]

Sto Bo Kr—Robert McClintock, Ann Arbor, Mich. Shipped between March 21 and May 24, 1940. Composition: essentially sulfuric acid, alcohol (77.5 per cent by volume) and water flavored with aromatics. Misbranded because statements: "The digestive remedy." Use it only until ailment ceases were false and misleading since the product was not efficacious as a digestive remedy and its use would not cause cessation of digestive ailments. Also misbranded because label did not give the common or usual name of the active ingredient, sulfuric acid, or the quantity, kind and proportion of alcohol present.—[D D N J F D C 320 September 1942] This product was one of the subjects of the Post Office fraud order issued July 14, 1938, debaring McClintock's quackish business from the mails, the details of which appeared in this department of THE JOURNAL Dec. 24, 1938, page 2409.

Watt Surgical—Watt Product, Inc., Springfield, Ill. Shipped Aug. 21, 1940. Composition: essentially water, formaldehyde, small amounts of turpentine and a yellow-green coloring material. Misbranded because falsely represented as an effective antiseptic, disinfectant, fungicide, germicide or parasiticide in the dilutions suggested or as a wet dressing or irrigation in wounds in these dilutions. Further misbranded because represented to penetrate the environment, inhibit disease-producing micro-organisms or be efficacious for sterilizing surgical instruments.—[D D N J F D C 324 September 1942]

"SYPHILIS AND THE NEGRO"

To the Editor—The article by Dr. Smilie in the June 5 issue of THE JOURNAL concerning syphilis and the Negro, and the editorial comment, serve to give needed emphasis to an important problem. But in characterizing the problem as a purely Negro one there is grave danger of overlooking some important facts concerning the treatment and prevention. Why is the syphilis rate so much higher in the Negro than in the white? To quote Dr. Smilie, 'Among the whites syphilis has become, in the great majority of cases, a disease of the ignorant, the careless, the criminal and the social outcast.' Do not the same conditions apply to syphilis in any group? The Negro is discriminated against economically and educationally, it would be difficult to find conditions more favorable to the development of crime, carelessness and social ostracism than the poverty and ignorance engendered by the wage and educational differentials that are too often the lot of the Negro. In this connection the chart published with your editorial comment (p. 378) is quite significant. It shows educational deficiencies as a cause, second only to syphilis, of rejection of Negro males by Selective Service local boards, whereas this factor did not appear in the first ten causes of rejection in the white group. This is more than a mere coincidence. It would be a serious mistake to attempt to treat this problem by merely dispensing large quantities of antisypilitic drugs without at the same time attempting to cure some of the serious socioeconomic conditions underlying it.

ROBERT E. FULLILOVE JR., M.D., New Orleans

To the Editor—In the article "Syphilis in the United States Primarily a Negro Problem" (THE JOURNAL, June 5, p. 365) and the emphasis and further presentation of statistical evidence (p. 378) I am impressed not only with the implications of the biometrical conclusions reached but more especially with the apparent lack of appreciation of the underlying medicosocial problems which are universal and which know no racial barriers or identification.

1 A low economic level with its slums, overcrowding, poor nutrition, poor recreational facilities, lack of certain cultural opportunity and educational advantages and other means of sublimative practice would tend to facilitate the spread of infectious disease in general and syphilis in particular.

2 A more practical effective, intensified, educational program which would reach the innermost recesses of the population would not only acquaint them with the scourges of venereal disease but would serve to create eventually a higher sense of values generally.

3 These things are not characteristic of any particular race of people but are broadly applicable to sociologic concepts in which disease, famine, poverty and the other scourges of the human race fall heir principally to the low educational-economic stratum of human society.

4 The large percentage of the Negro population incidentally fall into this group, a selective relative analysis of this group as a whole would reveal little if any difference in racial incidence.

5 The medical profession as a whole could be an effective force in achieving the correction of this basic fault in our society, which is first sociologic and, second, medical.

W. C. SAMPSON, M.D.,
General Hospital No. 2,

PREVENTION OF INFANTILE PARALYSIS

To the Editor—In view of the approaching season for possible poliomyelitis epidemics, it seems wise to summarize possible suggestions for limiting the spread of the disease. These suggestions are founded on present day knowledge, viz:

In the presence of the disease in a community:

1 Avoid the use of any water that is possibly contaminated with sewage either for drinking, swimming or washing utensils. We know that sewage can carry the virus considerable distances and for an appreciable time.

2 Avoid exhaustion from exertion or chilling. We know that overexertion and chilling during the incubation period tend to augment the oncoming disease.

3 Avoid injury to the mucous membranes of the nose and throat, such as that resulting from a tonsil operation. We know that poliomyelitis exposures in the early post-tonsillectomy period are liable to result in severe—even fatal—infections, usually of the bulbar type.

4 Treat every minor illness as a possible case of poliomyelitis, particularly if there is fever, headache and some spasm of the neck, spine and hamstrings. We know that very mild cases of poliomyelitis without recognizable paralysis are much more numerous than paralytic cases. Suspected patients should be kept quiet in bed for several days, and until passed as well by a competent examiner.

5 Strive for proper sanitary conditions and, in particular, destroy flies and their breeding places. We know that flies can carry the causative virus of poliomyelitis, although it has not yet been proved that they can carry enough to infect human beings.

6 Avoid unnecessary physical contacts with other people, wash hands carefully before eating, and don't put unclean objects in the mouth. We know that many healthy people carry the virus in their intestines and that for some cases, perhaps most, the point of entry of the infection is the mouth.

7 Don't prescribe or take drugs or chemicals that are intended to protect against the disease. As yet we know of none that will do this.

PHILIP M. STIMSON, M.D., New York

COLOR BLINDNESS

To the Editor—The editorial on color blindness and conclusion was read with interest. In this connection may I relate an experience I had during routine physical examination of men applying for positions in a large industrial plant. I found an applicant who was color blind and informed him of his condition, as in the type of work required of the applicant color blindness did not enter into the question of accepting or rejecting him for the position. I casually inquired what work he was doing before coming here and he replied that he was a color matcher in a cloth manufacturing concern. This aroused my curiosity and I asked him to tell me frankly how he was able to get along as a color matcher when he was definitely color blind. He replied 'The boss would bring a paddle which was colored and told me to match it, which I did.' He never asked what color the paddle was. Which shows that over a period if a person is instructed in the right color he is looking at he can in time learn to call the correct color, even if to him it seems like a different color.

MEDICOLEGAL ABSTRACTS

Malpractice Failure to Notify Appropriate Health Officer of Inflammation in Newborn's Eyes—The plaintiff's eyes were swollen more than normal when he was delivered by the defendant physician April 4 1940. At the physician's direction silver nitrate drops were instilled in the eyes. On April 7 when the physician next saw the child the eyes were still a little swollen and there was some discharge from both eyes, which the physician attributed to the silver nitrate. When he next called April 11 a nurse directed his attention to the fact that there was a continued swelling in and discharge from both eyes and that in the left eye there was something on the ball that appeared like a blister which would not wash off with the boric acid solution 'he had been using' at the physician's direction. After examining the eyes the physician assured the mother that they were perfectly all right and would be O. K. and prescribed a 5 per cent solution of mild protein silver. The physician was notified on the 15th that the swelling in the left eye and the spot in its center were more pronounced. The next day the child was taken to the defendant's office. The left eye was bulging and had a grayish appearance or a dull appearance. The physician suggested a consultation with an eye specialist and an appointment was made for the following day, but before that time the eye ruptured. When it failed to respond to treatment it was removed May 6. Suit for malpractice was subsequently brought against the defendant, it being alleged that the spot in the left eye was a corneal ulcer which by prompt use of available treatment could have been cured. The physician claimed that the condition was due to a congenital weakness and that the eye could not have been saved by any known treatment. From a judgment for the physician the plaintiff appealed to the court of appeals of Ohio Williams County.

An Ohio statute (General Code, Section 1248-2) makes it the duty of a physician attending at a childbirth and knowing within two weeks after birth of inflammation, swelling, redness or unnatural discharge from the eyes of the infant [by statute defined as 'inflammation of the eyes'] within six hours to report such fact as the state board of health might direct to the appropriate local health officer. The local health officer in turn is under a statutory duty (1) to transmit the report to the state board of health (whose duties were subsequently assumed by the state department of health) and to conduct such investigation as the state board shall direct and (2) to conform to such regulations as the board may promulgate (*ibid* section 1248-3). The state board is required by statute to provide if necessary daily inspection and prompt treatment to an infected infant (*ibid* section 1248-4). A regulation of the state board in addition to rules as to how physicians must report, which rules are substantially as specified in the statute provides that, if 'the condition or the case so requires in addition to the written report, an immediate notice of such case shall be given to the health commissioner in the most rapid manner available'.

The plaintiff alleged as a ground of negligence on the part of the physician that the physician failed to report to the local health officer that the plaintiff was suffering from inflammation of the eyes. The trial court withdrew that allegation from the consideration of the jury and its action was urged as error on appeal. The appellate court held that the trial court erred in so doing and as authority for so holding relied on *Medlin v Bloom* 230 Mass 201, 119 N. E. 773, and on *Jones v Stanko* 118 Ohio St. 147, 160 N. E. 456.

In the *Medlin* case the attending physician was sued by a child who had lost the sight of both eyes soon after birth. The birth occurred April 14, swelling in the eyes was observed April 22 and the physician was called on the 24th but did not respond to the call until the evening of the 25th. The evening of the 26th he called again and thereafter reported the case to the board of health by mail. The board promptly caused the child to be sent to a hospital for special treatment, but it did not avail. A Massachusetts statute required the attending physician to give immediate notice to the appropriate board of health if one or both eyes of the infant became inflamed, swollen and red and showed an unnatural discharge within two weeks after birth. The trial court in that case refused to instruct the jury that if it found that the physician violated the statute that violation would be evidence of negligence on his part. The appellate court in Massachusetts in that case said:

Upon this record it could not properly have been ruled as matter of law that the delay of the defendant in notifying the board of health of the plaintiff's condition was not evidence of negligence. It was for the jury to determine whether the defendant immediately gave the notice required by the statute. If he failed in this respect such failure was evidence of negligence which could have been found to have resulted as a proximate cause of the plaintiff's blindness.

The *Jones* case involved the failure of a physician to comply with an Ohio statute which required a physician attending a person suffering from smallpox to report the case to the appropriate health officer, who in turn was required to report the matter to the board of health, which was to cause an inspection to be made and a quarantine established. As a result of the defendant physician's failure in that case to make such a report, the plaintiff's decedent died from smallpox contracted from the physician's patient. The trial court in that case refused to instruct the jury that, if it found that the physician failed to comply with the provision of the statute and that such failure was the proximate cause of the death of the decedent, the verdict should be for the plaintiff. The action of the trial court in this regard the appellate court in Ohio in that case held was prejudicial error, and a judgment in favor of the physician was reversed.

In principle, said the court of appeals, the effect of failure to give notice was the same in this case as it was in the *Jones* case. From the undisputed evidence, the condition of the plaintiff's eye and the defendant physician's knowledge of it were such on April 11, if not before, that he should have reported it, and his failure to do so was a violation of the statute. In this respect the situation is more unfavorable to the physician than it was in the *Medlin* case, in which a report was actually made, and the jury question was whether it was made within the time required. If not, the court in that case said it "could have been found to have resulted as a proximate cause of the plaintiff's blindness." What would that court have said had no report ever been made? Can it be said that because this defendant completely ignored the statute he can escape any civil responsibility which may follow from his dereliction of duty? This question is decisively answered in the *Jones* case. The defendant physician here urged that the treatment that the plaintiff might have had had the statutory notice been given would only have resulted in a chance of recovery, which is not enough to sustain a verdict. But, answered the appellate court, there was positive evidence that the plaintiff's affliction was a corneal ulcer which was curable, not might be curable, which tended to prove that he had more than a "chance of recovery" had proper treatment been provided. Whether the condition was a corneal ulcer and could have been cured were matters for the jury to determine.

At the trial the testimony of the specialist to whom the defendant physician referred the plaintiff was received in evidence by a deposition. He was called by the plaintiff and on direct examination his testimony related only to the identity of material from the enucleated eye, part of which had been used in making some slides for microscopic examination by

other medical expert witnesses who testified for the plaintiff. On cross examination, the defendant qualified this specialist as an expert witness over the plaintiff's objection that the proceeding was improper cross examination, interrogated him concerning the condition that he found in the eye and concerning his opinion as to what had caused that disease condition and made necessary the removal of the eye. This cross examination was assigned as error by the plaintiff. The Ohio rule on the limits of cross examination, said the appellate court, is stated in the syllabus in *Ligg v Drake*, 1 Ohio St 286, as follows:

When a witness is produced and examined by a party in an action even though he be interested to testify against the party calling him the other party is not limited, in his cross examination to the subject matter of the examination in chief, but may cross examine him as to all matters pertinent to the issue on the trial, limited, however, by the rule that a party cannot before the time of opening his own case, introduce his distinct grounds of defense or avoidance, by the cross examination of his adversary's witnesses.

The pleadings and evidence in this case, said the appellate court, raised but two questions as determinative of the ultimate issue, the liability of the defendant physician, namely, (1) Was the defendant negligent as charged and (2), if so, did such negligence proximately cause the plaintiff's damage? The only defense was a general denial. On these questions the plaintiff had the burden of proof. The defendant had no "distinct grounds of defense or avoidance." Hence any relevant and material evidence was "pertinent to the issue on trial," and no error was committed by permitting the cross examination objected to.

The measure of a physician's duty to his patient, said the court, is stated in *Gillette v Tucker*, 67 Ohio St 106, 65 N E 865, as follows:

A surgeon and physician, employed to treat a case professionally, is under an obligation, which the law implies from the employment to exercise the average degree of skill, care, and diligence exercised by members of the same profession, practicing in the same or a similar locality in the light of the present state of medical and surgical science.

Certain instructions tendered by the defendant physician and given to the jury attempted to lay down a measure of a physician's duty to his patient in various ways, but in all of these instructions the element of "diligence" was omitted. The element of diligence, said the appellate court, was particularly important in this case, for it appears that the derelictions of duty with which the defendant physician was charged were mostly those of omission. It is manifest that some unhealthy condition existed in the plaintiff's eye which was not caused by the defendant. The real question is Did the physician fail to do something that his duty required him to do promptly which had it been done would have resulted in cure of that unhealthy condition and prevented the loss of the eye? Hence "diligence" was the all important element, and its omission from these instructions was misleading to the jury and rendered the instructions prejudicially erroneous. The element of "diligence" was also omitted in other instructions given to the jury which spoke only of treatment but were silent on the failure to treat. Particularly in one of these instructions it told the jury that "If you find that the sole proximate cause of plaintiff's injury was a condition which existed at the time of his birth, you should return a verdict for the defendant." This instruction failed to take into account the possibility that the jury could find that had the defendant employed the care, skill and diligence the law required of him, the "condition which existed at the time of birth" could have been cured.

Because of the errors noted, the judgment in favor of the physician was reversed and the cause was remanded for a new trial.—*Dutsch v Mayberry* 47 N E (2d) 401 (Ohio, 1942)

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodical published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Leukocytic Index—The leukocytic index is established by dividing the number of polymorphonuclear leukocytes (neutrophils) by the number of lymphocytes or by dividing the polymorphonuclear percentage by the lymphocyte percentage. It is not necessary to consider the numbers of any other cells since these two types of cells are by far the most important in resistance to disease, especially to infectious and toxic states. Turley and McClellan compared the leukocytic index with the clinical course in various infectious cases in the University Hospital. An average normal leukocytic index was established by making blood counts on 7 healthy persons with normal hemograms and computing the index. The indexes so obtained were 18 18 14 15 28 and 18. This would make an average normal index approximately 18. The authors present 11 cases in which the neutrophilic-lymphocytic ratio was compared with the clinical course. The cases presented various types of infection. Similar characteristic reactions were observed in all of them. The authors agree that the leukocytic or lymphatic index is a valuable indicator of the condition of the patient. It is a reliable factor in prognosis of infectious diseases and is an aid in determining the optimal time for surgical procedures. A high or rising leukocytic index indicates low resistance and a prognosis the seriousness of which is in proportion to the height of the index. A low or falling leukocytic index shows a high or increasing resistance and a prognosis the favorableness of which is in proportion to the smallness of the index.

Diagnosis of Large Gastric Ulcers—Steigmann analyzes more than 200 cases of large gastric ulcer seen on x-ray study at the Cook County Hospital in the last ten years. The results make him question the value of the signs and symptoms thought by some to be typical of benign or malignant ulcers. Only microscopic examination of the resected lesion can give the exact diagnosis. Sections for such study must be taken from various parts of the large ulcer crater, its walls, floor and margins before a definite opinion can be given. Failure to follow this precaution has resulted in the death of patients from carcinoma several months after the resected lesion was reported benign. The therapeutic implications are clear. Resection of every large gastric ulcer is advisable not only because of the danger of an erroneous diagnosis but also because complications of large ulcers make them really malignant when they are microscopically benign. It is doubtful that there is such a thing as complete healing of a large gastric ulcer on medical treatment. In view of the complications that may arise even when a large ulcer is benign and the possibility that they may be carcinomatous, one should not be content until such a lesion is resected.

Lipid Nephrosis—Lipid nephrosis as a distinct clinical entity is rather infrequent. In over twenty years in the pediatric service at the Mount Sinai Hospital Schwarz and his co-workers have made such a diagnosis for only 40 children. In that same period they observed over 400 children with typical symptoms of acute or chronic glomerular nephritis. Twenty-two of the 40 patients have died. The surviving children have been seen regularly at least three times during the year 8 or they have been under observation for from seven to twenty years. Four of the older group showed in later phases hypertension, occasional albuminuria and increased Addis counts. The others with 1 exception have at present an increased Addis count and no hypertension. The authors believe that these patients had a glomerular nephritis from the onset. The nephrotic syndrome would then be a phase in the life cycle of the disease. The improvement of some of the patients after an

acute infection, such as measles, is important. The authors cannot give a satisfactory explanation for the mechanism which makes the kidney less permeable to albumin, and induces diuresis. Such improvement is not noted in chronic glomerular nephritis. The microscopic studies on 12 necropsies revealed a histologic picture of the glomeruli different from that seen in chronic glomerular nephritis. A patient first seen with a typical clinical picture of acute glomerular nephritis with gross hematuria manifested within the next few typical symptoms of lipid nephrosis. The patient died of peritonitis. The necropsy showed marked glomerular changes. The authors conclude that most children with the classic clinical picture of lipid nephrosis have a glomerular involvement but perhaps in a different form from that seen in chronic or subacute glomerular nephritis.

Urinary Antiseptics and Escherichia Coli—Heimholz demonstrated great variation in the effect of sulfathiazole on twenty-one strains of *Escherichia coli*. Twenty more strains were tested for the bactericidal action of sulfathiazole. The results indicated a low resistance of all but four strains of *Esch. coli* to sulfathiazole. When the concentration of sulfathiazole was increased from 2 mg. to 200 mg. per hundred cubic centimeters, three of the four resistant strains were killed off. At the highest level, 200 mg. per hundred cubic centimeters, strain 22 still grew actively when it was inoculated in numbers of less than 100 bacilli to 0.5 cc. of urine. The author investigated the bactericidal effect of various concentrations of the drug on four strains, two highly resistant and two only slightly resistant. The most striking deduction to be drawn from these investigations is that the maximal concentration of sulfathiazole at which different strains of *Esch. coli* resist its bactericidal action may vary from 0.1 mg. to more than 200 mg. per hundred cubic centimeters. Although the number of strains resistant to sulfathiazole is small, the resistance of the infecting strain may account for the failure of therapy in any particular case. The second significant feature is that the size of the inoculum of bacteria may determine the bactericidal action. The author reports studies on the resistance to other urinary antiseptics applied to the two resistant strains. He tried out four different procedures: antiseptics resulting from (1) acidity, (2) mandelic acid, (3) methenamine mandelate and (4) methenamine. He found that strains resistant to sulfathiazole were also resistant to urinary acidity and mandelic acid but were more susceptible to methenamine and methenamine mandelate than nonresistant strains. Bactericidal action of sulfanilamide, sulfapyridine, sulfathiazole, sulfadiazine and sulfacetamide on these four strains gave the impression that sulfathiazole and sulfadiazine are more effective against *Esch. coli* than sulfacetamide, sulfapyridine or sulfanilamide. In concentrations of 0.5 mg. per hundred cubic centimeters sulfathiazole is more effective than sulfadiazine.

Renal Lesion Following Use of Sulfanilamide—Curtis and Sobin found that in vitro solubility of acetylsulfathiazole increased at a given pH in proportion to the specific gravity of the urine. Theoretical considerations and experimental data suggested to Sobin and his associates that the responsible factor in the increase of solubility of these materials in more concentrated urines was probably an increasing amount of urea. Forty-eight adult white male rats were divided into four groups of 12 and treated as follows. Groups 1 and 2 were each given

1 mg. of sodium acetylsulfapyridine per gram of body weight, but in addition group 2 received 5 mg. of urea per gram of body weight. Groups 3 and 4 received 3 mg. of sodium acetylsulfapyridine per gram of body weight and group 4 received in addition 10 mg. of urea per gram of body weight. Untreated rats of the same age were used as controls. The drugs were administered in solution through a stomach tube. The volume of solution of sodium acetylsulfapyridine was calculated on the basis of rat weight, and the urea was added. Animals were treated over periods of seven to fourteen days. The daily water intake and the weight were noted. Serial sections of both kidneys were studied. The authors concluded that 1. Intrarenal foreign material following sulfonamide drug therapy is of two types, precipitated sulfonamide and its acetylated products and cellular debris with calcium and iron deposited around or on this material. 2. Urea simultaneously administered with sodium acetylsulfapyridine will prevent the precipitation of sulfonamides and formation of renal calculi in rats. 3. The action of urea is independent of a diuretic effect and is due to a specific solvent action on the acetylsulfapyridine. 4. The nephrotoxic properties of acetylsulfapyridine are mechanical in nature and result from precipitation of the drug in the renal tract. 5. Calcification and the resultant renal calculus formation in sulfonamide treated animals is dependent on local tissue damage and secondary deposition of calcium and iron on focal, nonviable structures.

Treatment of Syphilis with Clorarsen—According to Kampmeier and Henning, clorarsen (3-amino-4-hydroxyphenyl dichlorarsine hydrochloride) has been used experimentally in the treatment of syphilis at Vanderbilt University Hospital for the past twenty months. The drug is closely allied to arsen oxide, to which it is probably converted within the body. A total of 4,348 doses have been given to 251 syphilitic patients. A single therapeutic dose produced dark field negativity within twenty-four hours in 42 of 45 cases of infectious syphilis studied. Healing of acute lesions was prompt. Chancres were healed by the end of the fourth week, all secondary and secondary relapse lesions were healed by the end of the fifth week. Over 50 per cent of the primary and secondary lesions were healed by the end of the second week. The reversal of the Wassermann and Kahn reactions under continuous antisyphilitic treatment with clorarsen and bismuth compounds was 100 per cent in primary syphilis by the seventeenth to the twenty-first week and 91 per cent in secondary syphilis by the twenty-first to the twenty-fourth week. The probability of the reversal of

the Kahn reaction in acute syphilis was delayed over that of the Wassermann reaction. Seroreversion in early latency is definitely later than in acute syphilis. Chlorarsen did not cause serious untoward reactions. Nausea, vomiting and diarrhea were the most common reactions. The drug was often used without reaction for patients who had had untoward reactions with other arsenical preparations.

Cardiac Symptoms in Mediastinal Distortion from Pulmonary Tuberculosis.—Brumfiel describes observations on 38 tuberculous patients with distortion of mediastinal structures and cardiac symptoms without a demonstrable cardiovascular disease. Evidence indicates that the distortions may cause cardiac symptoms. He had reported 15 such cases in 1933. Criteria for classifying the patients were (1) cardiac symptoms, (2) demonstrable distortion of the mediastinum by physical signs and roentgenograms (3) a past history free from known heart disease or infections recognized to affect the heart such as acute rheumatic infection or syphilis, and (4) absence of physical signs or cardiovascular disease and absence of other concurrent disease such as syphilis or hyperthyroidism known to affect the cardiovascular system either organically or functionally. As possible causes of mediastinal distortion in the tuberculous the author lists atelectasis of a lobe or of an entire lung fixation and contraction of a thickened pleura following effusion, fibrosis and contraction of the pulmonary parenchyma and therapeutic pneumothorax. Distortions of the mediastinum may be either to the right or to the left. They may involve the entire mediastinum or be limited to the superior portion. The physical signs are variable. A loud systolic murmur is heard frequently over the pulmonary conus in distortion of the superior mediastinum to the left and occasionally over the aorta in right sided deformity. The commonest complaint was dyspnea in excess of that to be expected on a purely pulmonary basis. The symptom complex consisted generally of dyspnea, palpitation and weakness with or without arrhythmia. One remarkable fact is the free interval between the establishment of the deformity and the onset of symptoms. There is no actual proof that distortion of the mediastinum and its contents may cause cardiac symptoms. Yet coincidence does not seem sufficient to explain that 38 such cases should be encountered by a single observer. The inference of a causal relationship seems inescapable. The improvement seen in certain cases after thoracoplasty presents additional evidence.

Heart in Pulmonary Tuberculosis.—Roberts and Lisa report clinical and pathologic observations in 100 cases of active pulmonary tuberculosis. Demonstrable myocardial lesions were present in 69. They consisted of tuberculous myocarditis in 10, acute rheumatic myocarditis in 1, Aschoff body-like lesions in 9, acute interstitial myocarditis in 50 and acute miliary infarctions in 11. Combinations of the lesions were found in 13. Healed

rheumatic valvulitis was found in 5, sclerotic lesions of the mitral and aortic valves in 20, acute valvular endocarditis in 2 and syphilitic aortic valvulitis in 2. There were 3 instances each of tuberculous, chronic adhesive and acute nontuberculous pericarditis. Tuberculous myocarditis was more frequent in adults than in children. Nontuberculous pulmonary infections appeared to be a significant factor in the causation of the interstitial myocarditis. Miliary infarctions occurred predominantly in hypertrophied hearts, in hearts with severe coronary arteriosclerosis and in the later decades of life. The conception of a small heart in tuberculosis was not substantiated. Right ventricular hypertrophy was uncommon. Mensuration of the ventricular wall appeared to be an unreliable criterion for hypertrophy. The microscopic appearance of the myocardial fibers appeared more accurate. Disproportion between pulse rate and height of temperature was suggestive of myocardial disease. Murmurs due to organic valvular lesions were fairly common. Functional murmurs were uncommon. The conception that hypertension and active tuberculosis are incompatible was not borne out. Electrocardiographic tracings frequently revealed significant observations.

Air Embolism in Pneumothorax.—Bohorofoush states that air embolism following pneumothorax has been attributed to air entering the pulmonary vein and passing into the heart and the arterial system. This concept is not substantiated by manifestations in all of the cases. The explanation has been only partially satisfactory. Air is not found constantly in the heart or carotid arteries at necropsy, nor has the method by which air enters the pulmonary vein been adequately clarified. The author reports 2 cases which constitute his experience with this accident in over 10,000 inductions of pneumothorax. Necropsy in the fatal case failed to reveal injury to the lung. Air embolism was characterized by pain in the chest during the induction of air onset of symptoms after the vertical position has been assumed and a latent period of a few seconds between the time of rising and the onset of symptoms. The clinical manifestations are similar to an attack of epilepsy; they consist of convulsions, Cheyne-Stokes respiration and tumultuous heart action. The transmission of air through the pulmonary veins in all cases is doubtful. The air may enter the veins in the thoracic wall and thence reach the cranial cavity through the superior vena cava or the vertebral system of veins. The following suggestions are made for the prevention and treatment of this condition. Never give air unless the manometric readings are satisfactory. Technical difficulties should be corrected after removing the needle from the thoracic wall. At the first indication of unexplained or unusual pain the needle should be removed and the head and trunk lowered. In aspirating fluid the syringe should not be removed from the needle or air introduced until fluid has been aspirated. If air embolism occurs, it is necessary to lower the head and trunk until the superior vena cava is below the level of the heart.

Shiga Toxoid—Farrell describes a method of preparing and treating with solution of formaldehyde a toxic extract of *Shigella dysenteriae*. A toxin was prepared by autolysis of a "smooth" culture of *Shigella dysenteriae*. Incubation of the toxin at a reaction of from pH 8.5 to pH 8.8 with 1 per cent solution of formaldehyde yielded materials which were nontoxic for mice and rabbits in intravenous doses of 0.5 cc and 5 cc. Mice injected subcutaneously with a total of 0.5 cc of detoxified material ("toxoid") in three equally spaced doses resisted up to 50 minimum lethal doses of toxin intravenously. Mice which had received subcutaneously 15 serum units of antidyenteric serum resisted, about twenty hours later, an intravenous dose of fifty minimum lethal doses of toxin. Rabbits which received three doses of toxoid derived from a total of 0.5 cc of toxin developed from 15 to 15 serum units of antitoxin per cubic centimeter of serum. A "secondary stimulus" of about 0.085 cc given one month after the third dose increased the titer of antitoxin from 15 to 65 serum units per cubic centimeter. Thirteen normal human subjects received from 1 to 9 injections of 0.1 to 0.5 cc of toxoid without undue reaction. Two doses of 0.25 cc evoked the production of antitoxin to a level of from 0.4 serum unit per cubic centimeter to 10 serum units per cubic centimeter in 7 of 8 subjects. After a third dose of 0.25 cc all 8 subjects had a measurable amount of antitoxin. Of 7 subjects presumed on epidemiologic grounds to have had Shiga dysentery, 6 had measurable amounts of specific antitoxin (from 13 to 14 serum units per cubic centimeter) at least one year after recovery. Ten days after an injection of toxoid, these 6 subjects had a definitely increased titer of antitoxin (from 10 to 65 serum units per cubic centimeter). The seventh subject still had no detectable antitoxin (less than 0.3 serum unit per cubic centimeter).

Prognostic Significance of Pneumococci in Sputum in Pneumonia—Frisch and his associates determined the average number of pneumococci per oil immersion field in Wright stained smears of rusty sputum at twelve hour intervals in 175 cases of pneumococcal pneumonia exclusive of type III. The close relationship between the highest sputum count during the course of the disease and the outcome was shown by the fact that the fatality rate was 2 per cent when the pneumococci did not exceed 10 per field, 9 per cent when 11 to 30 were present, 30 per cent when 31 to 75 organisms were found, and 77 per cent

cent when the number exceeded 75. The fatality rate was uniformly low in patients with less than 30 pneumococci per field and uniformly high in those with sputum counts above 30, regardless of the type of pneumococcus, duration of the disease prior to therapy, leukocyte count and blood culture. The unfavorable prognosis usually attributed to type bacteremia, leukopenia and late pneumonia was due chiefly to the higher incidence of sputum counts over 30 per field in such cases. On the other hand, a comparison of cases whose sputum counts fell within the same range showed that age and extent of consolidation had a definite effect on the outcome since the fatality rate was significantly higher in patients over 54 or in those with consolidation of 2 or more lobes on admission to the hospital. It was concluded that the number of pneumococci in the sputum had the greatest influence on prognosis and that the most important accessory factors were the extent of involvement and the age of the patient. It was also found that modern chemotherapeutic agents (sulfapyridine, sulfathiazole and sulfadiazine) did not appreciably reduce the fatality rate in cases with sputum counts below 30 but were distinctly superior to sulfanilamide and serum in cases with counts above 30. The combination of serum and drugs appeared to be no more effective in the latter group than chemotherapy alone. The utilization of the sputum as a method of prognosis in pneumonia has simplified the statistical approach to this disease. All new drugs submitted for clinical trial could first receive preliminary study in selected patients with initial sputum counts of 20 or less. The efficacy of the drugs could be evaluated in these patients by repeated examination of sputum to determine whether or not they were capable of reducing the number of pneumococci as rapidly as sulfathiazole or sulfadiazine. If the sputum count failed to decrease or actually increased within a specified time, therapeutic agents of proved value could be readily substituted without subjecting the patients to unnecessary hazards. The most promising drugs could then be studied in cases with more than 30 pneumococci per field in the hope that they might effect a significant reduction of the high fatality rate which still obtains with sulfathiazole and sulfadiazine in this group.

Prognostic Significance of Reticulation in Type III Pneumonia—Frisch and his collaborators show that the type III pneumococcus differs from all other pneumococci in its capacity to produce excessive amounts of capsular polysaccharide, as manifested by a fibrin-like reticulum in Wright stained smears of rusty sputum. In 114 cases of type III pneumonia reticulation in the sputum was by far the most important factor in determining the outcome. Thus the fatality rate was 79 per cent when reticulation was present and only 7 per cent when it was absent. Furthermore, fatality in reticulated cases was uniformly high regardless of the number of pneumococci in the sputum, the blood culture, the leukocyte count and the extent of the consolidation but was partially influenced by the factor of age. The unfavorable prognostic significance customarily attached to bacteremia and leukopenia in type III pneumonia was attributable to the fact that reticulation was almost invariably present in such cases. The outcome in the nonreticulated cases as in the other types, was dependent on the number of pneumococci per field in the sputum. Sulfapyridine and sulfathiazole were superior to serum and sulfanilamide in the treatment of type III pneumonia because they prevented the formation of reticulation and reduced the fatality rate in reticulated cases from 100 to 67 per cent.

Effect of Penicillin and Tyrothricin Against Sulfonamide Fast Pneumococci—The observations reported by Tillett and his associates were made on 2 patients with pneumococcal pneumonia and bacteremia. Pneumococci types I and VIII were isolated. These strains caused infections in mice that were totally refractory to sulfadiazine. The clinical course of the patients and the clinical laboratory data (blood cultures and sulfonamide concentrations in blood) also indicated the drug resistant characteristics of the infection. Both patients responded rapidly and successfully to specific therapy. In experimental observations penicillin was found to be highly effective against infections in mice caused by either sulfonamide resistant or susceptible strains. When tyrothricin in single

doses was used for treatment of mice, the protection was not uniformly complete against any one of the strains. No evidence was obtained to indicate that sulfonamide resistance influenced the effect of tyrothricin. It was not possible to demonstrate that the drug resistance of the patients' strains was due to the production of inhibiting substances. By contrast, cultures of an additional strain of type I pneumococcus (MacLeod) were found to yield considerable amounts of inhibitor.

Vaccination Against Influenza Type A—Henle and his collaborators studied the efficacy of allantoic fluid vaccines in the prevention of experimental human infection with the virus of influenza A. Of 28 control subjects 10 came down with clinical influenza following inhalation of a recently isolated active virus. Only 1 case which had not responded to vaccination occurred among the 44 vaccinated persons, 27 of whom had been immunized four months prior to the exposure. There was good correlation between the preinhalation antibody level and the degree of protection in that most of the clinical cases occurred in the group with the lowest antibody titer as measured both by mouse protection and by inhibition of red cell agglutination technique. Increase in the antibody level decreased the morbidity. The clinical picture of the experimental disease confirmed the observation of earlier investigators. Since a number of individuals harbored pathogenic organisms in the upper respiratory tract all clinical cases were treated with sulfonamides. No complications were encountered. Subclinical infections were numerous as shown by slight elevations of temperature mostly on the second or fourth day after inhalation, leukopenia below 5000 or rises in antibodies two weeks after the exposure. These symptoms were independent of one another, either one alone or any combination of the three could be found. Virus was reisolated only from clinical cases.

Experimental Studies on Lead Absorption and Excretion and Their Relation to Diagnosis and Treatment of Lead Poisoning. R. A. Kehoe, J. Cholak, D. M. Hubbard, K. Bambach and R. R. McNary—p. 71

Health of Lead Exposed Storage Battery Workers—A study of 766 storage battery workers by Dreesen disclosed that 177 were affected by early plumbism, 168 of these had abnormal lead absorption and 9 incipient plumbism. Only 4 per cent of the men exposed to less than 0.75 mg. of lead per 10 cubic meters of air showed signs of abnormal absorption whereas 54 per cent of those exposed to more than 3 mg. had early plumbism. There were no important time trends. Both blood and urinary lead values were higher in the affected workers. These values also increased with increasing atmospheric lead exposure. It appears that the more the blood or urinary lead values of an individual deviate from the range of unexposed persons the greater is the likelihood that such an individual will have other evidence of lead induced bodily changes. Reticulocyte stipple cell and polychromatophilia values correlated generally with atmospheric lead concentrations and blood and urinary lead values. Therefore these hematologic determinations are apparently of value for the periodic appraisal of employees exposed to hazardous concentrations of lead.

 Nasal Compression and Preordial Auscultation in Children I Ortiz Ramirez — p 165

Sulfapyridine in Colitis—Aguilar reports observations on a group of 28 children with acute and subacute mucosanguinous colitis which had developed in the course of various types of infection of the upper respiratory tract or in the course of otitis media. The pneumococcus was identified by the culture method from the feces of 18 and the streptococcus from the feces of 8 patients. Sulfapyridine was given in daily doses which varied between 0.1 and 0.15 Gm for three consecutive days. The same therapy was practiced in a group of 100 children. The disease was rapidly controlled in all of the cases. No instances of intolerance to the drug were observed.

Transurethral Resection of the Prostate—Diaz Muñoz and Lira Valencia present an analysis of 121 cases of transurethral resection of the prostate. In 2 cases resection was done for a congenital defect causing obstruction of the neck of the bladder. A perfect functional result was obtained. The second group included patients with acquired hypertrophy of the neck of the bladder either as the result of inflammation of the posterior urethra or as a sequel to previous intervention on the prostate. In this group there were no fatalities, and the functional results were good in all except 1. The third group comprised 67 patients in whom the hypertrophy involved chiefly the median lobe. These were selected patients, and the results were favorable. In patients of the fourth and fifth groups the lateral lobes were chiefly involved and in those of the sixth there was cancer of the prostate. In this last group transurethral resection is particularly indicated. Hemorrhage may be an immediate as well as a late complication. There were 6 of each in this series. Pulmonary or cerebral embolism did not occur. Various infections occurred, and they continue to constitute a serious problem. Repeated resections were necessary in some cases. X-ray examination of the kidney and pelvis should always precede the operation, since endoscopic resection is contraindicated in the presence of renal or prostatic lithiasis. A comparison of results obtained with this method and with the suprapubic operation revealed that the mortality over a course of four years was 13.2 per cent with prostatectomy and 11.1 per cent in resection. Neither method should be used exclusively, the surgeon must select the method best suited for the individual case. In many cases resection is less dangerous than the prostatectomy.

Electric Shock Treatment—Bosch and his associates show that Viale of Rosario, Argentina, originated the electric shock therapy later developed in Italy by Cerletti and Bini. The authors report 14 cases in which electric shock therapy was

employed. The therapy was also used in combination with the insulin coma (method of summation of Georgi) and alternately with metrazol shock (von Braunnubel's method). Electric shock is a simple and practical method of treatment of all psychopathies. It can be employed by producing either complete crises or incomplete crises according to the authors' method. The latter are produced by applying the current for one twentieth of a second instead of one tenth. By employing the current for a shorter period the authors were able to suppress the apnea and reduce the time of awakening. Contraindications to metrazol therapy, such as myocardial deficiencies, hypertension, febrile diseases, progressive tuberculosis, pregnancy, severe anemia and renal insufficiency, were observed in application of electric shock therapy. No serious accidents occurred. The incomplete crises have not as many contraindications as the complete crises and can be utilized for some patients with organic defects. The method has definite advantages over other methods of shock therapy. The aura is completely suppressed and there is amnesia as regards the crisis. It is more rapid and avoids the necessity of using syringes, needles and poor veins. The method proved particularly effective in stupor, melancholia and catatonia. These patients become much more amenable to other treatments, such as work therapy or psychotherapy. In the less fortunate cases the secondary symptoms disappeared and stimulation of the mental state became evident. Electric shock is also an excellent method of investigation which may advance our knowledge of epilepsy and its treatment.

Malignant Tumors of Kidney—Belchior reviews the clinical course of 94 cases of malignant tumors of the kidney observed at the urologic clinic in Cleveland. In 59 of these the diagnosis was confirmed by microscopic examination of tissue obtained by nephrectomy, biopsy or necropsy. Renal tumors are more frequent in men than in women (235:1). Approximately 25 per cent presented hematuria, pain and palpable tumor, the classic triad of symptoms. Hematuria was the initial symptom in 35 per cent, while it developed later in 18 per cent. Pain in the renal region, particularly along the course of the ureter, was the initial symptom in 28 per cent, in 35 others pain was preceded by other symptoms. An abdominal tumor was the initial symptom in only 5 per cent, but in 42 per cent a renal tumor could be palpated during the physical examination. Weakness and loss of weight were the initial symptoms in 11 per cent. Less frequent initial symptoms are swelling of a testicle, fever, sciatica and swelling of the feet or legs. Hematuria is the most frequent symptom and always calls for a thorough examination of the urinary tract. Cystoscopy and retrograde pyelography are the most reliable diagnostic methods. The tumors in this series originated in the parenchyma in 47 and in the renal pelvis in 12. The percentage of hypernephromas was unusually high. The treatment must take into account the age and general condition of the patient and the stage of advancement of the tumor, particularly the presence of metastases. Early recognition, together with radical resection, are the most important factors in controlling the malignant renal tumors. In view of the many possible variations in the clinical picture, the ease with which these tumors spread to other organs and the technical difficulties in complete extirpation, these methods will not result in a large percentage of permanent cures. In a considerable number of cases the cure would be appreciably prolonged, and there is always a chance that a complete cure will ensue.

Book Notices

The Principles and Practice of War Surgery with Reference to the Biological Method of the Treatment of War Wounds and Fractures By J. Trueta, M.D., Assistant Surgeon (F. M. S.), Wingfield Morris Orthopedic Hospital, Oxford, England. With Introduction by Owen H. Wankenstein, M.D., Minneapolis, Minn. Cloth. Price \$6.50. 1 p. 441 with 144 illustrations. St. Louis: C. V. Mosby Company, 1947.

The entire title must be made a part of the book review to attract attention to the point that Trueta rests his book on those fundamental principles of surgery by means of which the surgeon should obtain his results in the best possible manner and the patient his best recovery. Trueta's book enunciates these principles again very well indeed, but he permits himself as so many writers do, to be drawn aside into discussions of certain technical methods and chemical wound treatment which only serve to confuse the reader and lead him to employ details of treatment which disturb the patient and contribute little if anything to his defense against infection and his recovery.

In this book Trueta presents a program or technic which varies in certain details from the method proposed by Orr in 1923. But he says "It is to Friedrich and more particularly to Winnett Orr who above all others lighted the path I have followed that my gratitude is chiefly due. I have proclaimed this before, but there is no other or more fitting note on which I would wish to introduce this book."

Two recent writers, Ponseti and Puig, surgeons in Barcelona in 1938, have also discussed these methods in a paper in *Orthopedic Medicine* (42:73 [March] 1943). They begin "One of the most important acquisitions in war surgery during our time was developed by the Spanish war experience. Statistics published by Trueta, D'Harcourt, Arguelles and Jimeno-Vidal show the best results obtained to the present time. Various technics were used by the different surgical schools, but a common characteristic was one which could be called 'the nonantiseptic treatment'—this is the complete discard of antiseptics as a treatment of wounds. Merely the strict observation of the basic principles of excision of the wound, immobilization and drainage sufficed to give the best results."

They continue "The Orr method is something more than a treatment for osteomyelitis. It is something more than merely to apply a vaseline pack over a wound and cover it with a plaster cast. It is a general surgical program based on a new and different understanding of the problem of wound infection and is applicable to all fields of surgery. The roots of the Orr method go deep into the biologic fundamentals of the inflammatory process."

With regard to this Trueta says that in 1934 he had treated 40 cases of osteomyelitis with the Winnett Orr technic and it occurred to him that he could employ the method in other more serious kinds of bone and joint infection. It had obviously not come to the attention of Professor Trueta that by 1934 probably a hundred papers had been published on the use of the Orr method in all kinds of acute and chronic infections of bones and joints and that Orr's book had been published by Mosby in St. Louis on *The Treatment of Osteomyelitis and Compound Fractures and Other Infected Wounds by Drainage and Rest*. This covered the entire field which Trueta was only entering at that time.

Trueta's modifications of the immobilization rest and intricate dressing program consist chiefly according to this book in omitting the primary application of iodine as a clean-up antiseptic agent for skin and wound surfaces, discarding the use of the petrolatum gauze pack in favor of dry gauze and the use of drainage by suction. Otherwise his program seems to be about the same as when he began in 1934-1938. Trueta has never made as extensive use of fixation with skeletal devices in the plaster of Paris cast as had already been employed for a number of years to insure correct length and position and immobilization during the postoperative period.

It seems a little strange now that instead of iodine Trueta advocates the use of the sulfonamides both in the wound and constitutionally. Also in the light of his research with regard

to the distribution of infection we should expect him to pay more rather than less attention to the importance of drainage and the protection of the wound against secondary infection. This last point arises because of his concessions in the discussion of primary and secondary wound closure. Any closure of infected wounds involves the risk of covering over or closing pockets of active or potential infection with all the dangers of flare-ups to which the patient is thus necessarily exposed. Trueta is inclined to assume as many others have done, that the surgeon can guess how much and how virulent the infection is that still lies inside a wound cavity or even inside a joint and to permit any surgeon to take for the patient the risk involved in finding out by clinical experiment whether or not the patient can take care of such an infected area after it has been closed by sutures.

Primary adequate drainage with gradual closure of the wound from the bottom would seem on the whole to be a safer procedure under all conditions and circumstances.

Dr. Trueta's clinical experience both in Barcelona and since that time had been so successful before he used sulfonamides and without some of the other variations in the technic which he now employs that one finds it difficult to reconcile these later modifications with his previous experience. Any one who has treated more than a thousand cases of severe gunshot shrapnel and other compound fracture injuries with only six deaths will find it difficult to improve on those results with sulfonamides, mobilization of neighboring joints in postoperative treatment, different kinds of drainage or other forms of wound or constitutional chemical therapy. It would seem better to adhere to such fundamentals as the primary clean-up of wounds, adequate drainage, immobilization in correct length and position and protection of the patient against irritative motion and damage to the wound surface. All of these are adequately and thoroughly recognized and described in Professor Trueta's book. He has done this so well that the variations in this program suggested by the introduction of various other details in technic would seem to be very much out of place. Moreover, the research in Barcelona and later in Oxford by Trueta and his predecessors and associates (see chapter IV) on the importance of immobilization in isolating infection in injured and infected extremities would seem to have rationalized so completely all of our teachings with regard to the value of immobilization in such cases that variation in this respect also would seem to be improper. We know as we never knew before how much depends on immobilization and correct position of all the parts in an infected or inflamed extremity—the muscles, nerves, blood vessels and lymph channels as well as the damaged bone and joint structure. This is essential to protect the patient against wound damage and the spread of infection and to assist him in his own efforts for both defense and recovery.

The remarks of Ponseti and Puig may well conclude this comment also. Rest is one of the basic principles of the Orr method. Since rest is recognized as essential in the treatment of osseous lesions, the Orr method had sometimes been interpreted as applicable only to this sort of lesion. In reality the Orr method is applicable to every sort of infected wound with or without involvement of the bones, although its advantages are most remarkable in the treatment of osteomyelitis inasmuch as good drainage is more difficult to obtain in the osseous tissue. As is well known, Orr places extreme importance on the factor of rest. Thomas's watchword "entrenched and prolonged rest" has perhaps never before been so carefully observed in practice as it has by Orr. The plaster immobilization applied by him is much more extensive than we have ever seen before. It has long been known that rest is favorable to the biologic defense process and that it is one of the basic conditions for tissue regeneration.

Trueta's book is a good book. It contains many suggestions of value for the military and civilian surgeon. But the book must be read with one's guard up against many of the innovations as to wound surgery and chemotherapy that threaten as usual to violate or vitiate methods that should always conform to principles and fundamentals. These can never be forgotten or ignored (like asepsis) even for a moment.

Exploring the Dangerous Trades. The Autobiography of Alice Hamilton, M.D. Cloth. Price, \$3. Pp. 133 with illustrations by Norah Hamilton. Boston: Little, Brown and Company, 1941.

Dr. Hamilton is one of the great pioneers in industrial hygiene. Her autobiography is a readable, diary-like record of her experiences in industrial hygiene intermingled with her thoughts and actions outside her professional field. Deep sincerity and a consuming desire to improve the lot of her fellow human beings are the strong motivating forces of her life as revealed here. Dr. Hamilton is best known in medical circles for her pioneer discoveries in lead poisoning. Her work carried her also into other industries and the investigation of other industrial processes: copper, picric acid and the air hammer, for example, but lead has remained the recurring theme of Dr. Hamilton's professional life. Although she speaks frequently of employers who resisted reform measures, the facts as presented record a degree of cooperation from employers which, on the whole, was better than might have been expected. The book contains many commentaries on the contemporary scene and contemporary persons not medical in nature. Although one may disagree with many of Dr. Hamilton's interpretations of men or events the nonmedical sections are fully as interesting as those dealing strictly with matters of industrial hygiene. One feature of the book which deserves special mention is the illustrations by Norah Hamilton the author's sister. The book has much charm in addition to the factual information it conveys.

The Anatomy of the Nervous System from the Standpoint of Development and Function. By Stephen Walter Ranson, M.D., Ph.D. Seventh edition. Cloth. Price, \$6.50. Pp. 520 with 108 illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

This, the extensively revised seventh edition of one of the most widely read neurologic textbooks, was completed for press a few days before the death of its distinguished author, and the revision stands as a fitting memorial to one of the foremost experimental neurologists of our time. The Anatomy of the Nervous System first appeared in 1920 and it has been revised with systematic regularity at intervals of three to four years since its appearance, it is especially gratifying to learn from the publisher's foreword that Dr. Ranson, with his usual foresight, had selected Dr. Sam L. Clark, one of his former pupils, now professor of anatomy at Vanderbilt University, as his successor for future revisions. Few selections could have been more appropriate, and the new editions will be as eagerly sought after as those which have appeared during the past twenty-three years.

The successive editions of Ranson closely reflect Dr. Ranson himself and the development of his interests. He commenced his scientific career with his well known study of the non-medullated fibers of the dorsal nerve roots (1911) and for many years his primary interests remained almost entirely in the sphere of neuroanatomic detail. In 1916 with Billingsley he began to study the vasomotor center. The first edition of his book, issued several years later, is almost wholly anatomic in emphasis with only occasional references to function, but Ranson had been stimulated by the vasomotor center and had begun to see the structural matrix of the nervous system in a more dynamic light. In the twenties he inaugurated studies on the physiology of posture, and thereafter problems of muscle tone began to slip into his textbook. After his appointment as director of the Neurological Institute at Northwestern in 1928 his interests became more and more dynamic, and during the last five years of his life his amazingly productive laboratory concerned itself almost wholly with studies of nervous function. For this reason the seventh edition has a new breath of life. In its pages we see Dr. Ranson with his many loyal student followers branching out in a dozen different directions translating anatomic facts into physiologic language. One finds an excellent but all too brief discussion of hypothalamic function, the cerebellum of Larsell and Dow has come into its own—indeed, Dr. Ranson gives the first adequate discussion of functional localization in the cerebellum to be found in any neuroanatomic textbook (other than that of Larsell). Similarly the extrapyramidal motor projections from the cerebral cortex have begun, but only just begun, to come into their own.

As usual, the book is admirably produced with many new and well selected illustrations. The book continues to be set in a

5 inch page, which, despite the length of line, is legible, but the text could be more compact and virtually as legible if there were less leading between lines and around illustrations, and general appearances could be improved by the choice of a blacker and bolder type face more suited for glazed paper. Cuts which have been old standbys from former editions no longer appear worn, and all evidently have been engraved anew. A minor criticism might be offered of figure 42, the illustration of the dermatomes, in which no attempt has been made to incorporate the exhaustive study of the dermatomes by the late Otfried Foerster. Neurologists throughout the world will welcome this new edition coming at a time when the engines of war are heaping insults on all levels of the cerebrospinal axis as well as on peripheral nerve.

Transurethral Prostatectomy. By Reed M. Nesbit, M.D., F.A.C.S., Associate Professor of Surgery, University of Michigan Medical School in Charge of the Section of Urology, Department of Surgery, Ann Arbor. A Chapter on the Vascular Supply of the Prostate Gland. By Rubin H. Flocks, M.D. Cloth. Price, \$7.50. Pp. 192, with illustrations by William P. Didusch. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

This attractive monograph on an important urologic surgical procedure represents an authoritative compilation of all worth while essentials for good transurethral surgery on the obstructing prostate gland. The author makes no claims for originality but carefully explains that the techniques and procedures are those employed in his first class university urologic department. As narrated by Dr. Nesbit, the techniques may well be used by all urologists and the setup might be adopted by any well regulated urologic department. The initial chapter on arterial distribution within the prostate gland, by Rubin H. Flocks, is complete in anatomic detail and serves as a background for the author's transurethral surgical approach. The original illustrations of William P. Didusch are beautiful and so completely descriptive that any urologist could follow Dr. Nesbit's surgical technique with absolute accuracy. An important detail of surgical procedure is Dr. Nesbit's determination of blood loss at the time of operation. Immediate replacement by transfusion is advised, and the author cautions against waiting for indications by post-operative blood counts. The historical review of the surgical procedure is not only interesting but extremely detailed, and the author has completed the first comprehensive bibliography on all phases of transurethral surgery and its correlated phenomena. A few misspellings and several grammatical errors warrant more detailed proof reading by the author's university editorial assistant. Despite this modest defect, this monograph should be extremely useful to the expert resectionist and should be an accurate guide for those venturesome surgeons who must delve into this highly technical realm of an exact surgical specialty.

Mark Pfeiffer, M.D. By John Weld. Cloth. Price, \$2.75. Pp. 324. New York: Charles Scribner's Sons, 1943.

Here is a novel typical of novels about doctors. It traces the career of a boy who is the son of a railway engineer in a typical small town Illinois family. In the interest of the family prestige the boy determines to become a physician. His ambitions cause him to disregard many of the social, moral and ethical values, so that he drives steadily forward to success as a surgeon. In this drive he passes through medical college in Chicago, an internship in the Cook County Hospital, an assistantship and finally a residency with a character poorly disguised but meant to reflect Harvey Cushing. The book is dedicated to Dr. Loyal Davis and no doubt the author has obtained much of his medical color from conversations with Dr. Davis. One character prominent in the book comes particularly to light, namely, the first wife of Mark Pfeiffer, who represents the rich playgirl type.

Doctors will find the book extraordinarily interesting because it tells about them and their work with the drama of a novel as the setting. There are many excellent reflections on the weakness as well as on the strength of medical practice. Certainly the writing by a professional novelist is well above the average of most works in this field. Compared, however, with Somerset Maugham's "Of Human Bondage," Francis Brown's "The Young Physician" or even some of Cronin's and Deeping's works, the book runs fifth.

Periodontia: A Study of the Histology, Physiology and Pathology of the Periodontium and the Treatment of Its Diseases. By Henry M. Gold, M.D., Instructor in Oral Pathology, Harvard School of Dental Medicine, Harvard University, Boston. (Cloth, Price \$7.50. Pp. 107, with 510 illustrations. St. Louis, C.V. Mosby Company, 1912.)

Diseases affecting the supporting tissues of human teeth are as old as the history of man. The pathology of periodontal diseases has been investigated only since the early 1920's, when Gottlieb published his observations on human necropsy material. The names of Kronfeld, Orban and others are closely associated with this work. The many advances that have been made in the treatment of periodontium in recent years are well described and carefully enumerated. The illustrations are clear and each is well explained. Each illustration tells a definite and significant story.

Chapter 1 is devoted to examination. Items of special interest are laboratory tests, blood examination, basal metabolism and urinalysis. Chapter 2 considers the diagnosis made after careful examination of the different manifestations of periodontal disease so that a differential diagnosis may be made of well defined types. X-ray examination is valuable as an auxiliary means of diagnosis; using gutta-percha points to determine the depth of pockets. The disease then should be classified as to cause and progression and the method and necessity of home care explained to the patient in addition to the corrective care administered by the dentist.

Chapter 3 deals with etiology and stresses particularly traumatic occlusion, autointoxication and faulty diet. Occlusal trauma is defined as a force in excess of that which can be borne by the tissues of the periodontium without injury. McLean describes three types of masticating derangement: interference with lateral and protrusive movements, performance of the masticating function in an eccentric relationship which he calls convenience relationship and which may develop into a case of malocclusion and centric interference; it the dentures strike on cusp ridges before sliding into centric position with particular damage to the bone from the resulting anteroposterior thrust. McLean believes that cuspal interference causes shorter and more nearly vertical movements of the jaw in the shearing stroke and in extreme cases leads to so-called locked bite. Occlusal derangements if existing for a long time result in tooth wear and periodontal disease. The more the teeth resist wear, the greater the damage to the periodontium. This exemplifies the condensed and precise concentration of etiologic factors found throughout the book. Traumatic occlusion must be carefully considered as a primary cause of periodontal disease as well as dietary and vitamin deficiencies. A bibliography at the end of the chapter contains many valuable references pertaining to all subjects discussed.

Chapter 4 takes up the pathology of periodontal disease, the knowledge of which is essential for scientific diagnosis and proper treatment. It gives a comparative picture of tissues, teeth and supporting structures from youth to old age. Again the subject of malocclusion and its effects is discussed in detail. Where a tooth is subjected to heavy stress the periodontal membrane becomes thicker while a tooth that is out of function has a thinner periodontal membrane. Temporary or permanent damage may thus be caused.

The alveolar bone reacts to occlusal conditions. The physiology of tooth suspension and the alveolar bone is discussed to explain these changes and the possibility of injury to the alveolar bone because of occlusal trauma sometimes causing resorption.

The main cause of gingival irritation is calculus. Other sources are overhanging fillings, faulty crowns and loss of contact. A fine differentiation of the three stages in periodontosis is described and pictured. The amount of discharge from a pocket depends on the degree of destruction of the crevicular epithelium and the amount of cellular infiltration of the sub-epithelial tissues. The depth of the pocket does not designate the amount of purulent discharge. A number of reference books are again named.

Chapter 5, the final chapter, is on treatment. The first recommendation is the employment of careful systematic routine methods correlated with the diagnosis and the pathologic and etiologic factors. Objectives are restoration of gum tissues to

a hard, firm, pink and healthy state, teeth firm and stable in sockets, free of infection and hopeless teeth removed and the masticating mechanism rebuilt, correcting traumatic stresses. Methods of treatment for various conditions are described in detail, supplemented by pictures. It is sometimes necessary to employ orthodontic measures to move teeth to their proper functional position.

It is impossible for a review or summary to do justice to such an important and valuable book. It merits a careful study rather than a casual reading.

Essentials of Gynecology. By Willard R. Cooke, M.D., F.A.C.S., Professor and Head of the Department of Obstetrics and Gynecology, University of Texas (Austin). (Cloth, Price \$6.50. Pp. 474, with 197 illustrations. Philadelphia, Montreal & London: J.B. Lippincott Company, 1913.)

The author states in the preface that his object in this book is to present concisely, from the practical viewpoint and with as much correlation as possible the salient features of the anatomy, pathology, symptomatology and therapy of gynecology. This he does successfully in most instances. However, on some subjects the material included is inadequate to meet the stated requirements.

Despite the fact that the book is intended primarily for general practitioners and medical students, the technique of bimanual examination is not presented, although other steps in the examination are. The section on anatomy, although brief, includes the more important features of pelvic structure and is clearly presented and adequately illustrated. The inclusion of a short chapter on psychologic factors and mode of life as related to gynecologic disease and frequent emphasis of the subject throughout the book is unusual in textbooks on gynecology. On the other hand, the author also attributes many psychoses and neuroses to the more common gynecologic lesions such as cervicitis and pelvic inflammation.

The division of subject material and the grouping of disease entities is unusual and occasionally confusing. For instance, in one chapter on functional disturbances are included normal intercourse, dyspareunia, menstrual disturbances, dysmenorrhea, neuroses and psychoses associated with menstruation, ovarian hyperfunction and hypofunction, sterility, contraception, therapeutic and spontaneous abortion and ectopic pregnancy. Intercourse processes are divided into surface and invasive neoplasms into benign and malignant epithelial and stromal, under each heading is discussed the disease process in each of the pelvic organs as contrasted with the more common presentations in which all conditions which may involve any one organ are discussed together. In the sections on preoperative and post-operative care are discussed the preparation of patients for operation and their care during the convalescence. Although the more common gynecologic operations are but briefly outlined, this is of little value to the student or general practitioner since there are no illustrations and the technical details are omitted.

The book is well illustrated both by line drawings and by photographs of pathologic material. Nearly all the illustrations are original, only a few having been reproduced from other published works. The photomicrographs in most instances are clear and show the tissue structure well. The publication of this book represents an excellent effort toward bridging the gap between the standard textbooks of gynecology and the outlines so commonly used by students.

Somatic and Endocrine Studies of Puberal and Adolescent Boys. By William Walter Greulich, Ph.D., and others. Monographs of the Society for Research in Child Development, Volume VII, No. 3 (Serial No. 33). Paper, Price \$1.50. Pp. 85, with illustrations. Washington, D.C.: Society for Research in Child Development, National Research Council, 1912.

This short monograph deals with the physical development of prepuberal and adolescent boys together with examinations of the urinary excretion of estrogens, androgens and gonadotropic hormones and correlation between the physical and laboratory studies. The monograph includes several plates illustrating differences in physical development in boys of the same and different chronologic ages. This study constitutes a useful contribution to the subject.

Queries and Minor Notes

THE ANSWERS HERE MUST HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES. LESS SPECIFICALLY STATED, THE RELAY ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLOOD GROUPINGS AND PLASMA TRANSFUSION

To the Editor—Persons belonging to type O (Landsteiner) are regarded as "universal" blood donors, and those belonging to type AB are "universal" recipients. In giving blood plasma, should not the reverse be true—with type AB the "universal" plasma donor and type O the "universal" recipient? If a burned patient with type AB loses most of his plasma into his tissues and receives massive plasma transfusions from any or all other group, will the recipient's cells be agglutinated? It is my impression that burned patients receiving large quantities of plasma often die. Might not some of this mortality be the result of recipient red cell agglutination?

Harvard L. Ramence, M.D., Springfield, Ill.

ANSWER—The terminology suggested for plasma in the query cannot be accepted because it presupposes that the transfusion of agglutinable blood and plasma containing agglutinins active or the patient's cells may be equally harmful. Fundamentally the issues involved in a discussion of reactions to injections of plasma do not differ from those dealing with reactions following the use of universal group O blood for patients of groups A, B and AB. In both cases the question concerns the role of the action of the isogglutinins injected. Experience has confirmed the validity of Ottenberg's suggestion made in 1911 that, by and large, the transfusion of universal donor blood to patients of groups A, B or AB can be carried out safely. Although isoagglutinins anti-A and anti-B capable of reacting with the patient's blood cells are administered in such a transfusion, the quantitative relationships are such that the foreign agglutinins are rendered inactive by dilution and specific absorption and inhibition.

In the usual transfusion of universal donor blood or of group O plasma, the comparatively small volume of 250 cc is diluted in the patient's circulation so that in the final mixture the isoagglutinins are specifically inhibited by an excess of the patient's red blood cells. An additional factor of safety is the wide distribution of the A and B agglutinogens in tissue cells and body fluids including plasma. Since there is always an excess of these substances in the body, the injected agglutinins are rendered harmless by fixation.

There is a possibility of some danger in the indiscriminate use of universal donor blood or plasma in a very anemic patient of group A, B or AB is repeatedly transfused. In treating massive hemorrhage it may be safe to give one transfusion of group O blood. While this is being done attempts should be made to find donors of the same group as the patient, and subsequent transfusions should be carried out with homologous blood.

In administering plasma alone there are other considerations which make it unnecessary to perform compatibility tests. In the great majority of the hospitals pooled plasma is employed, so that the average pool is derived from individuals of groups O, A and, to a lesser degree, group B. Accordingly the dilution and the specific inhibition of the activity of the agglutinin make it possible to administer the plasma indiscriminately, i.e. without employing preliminary compatibility tests. Even if one uses plasma not derived from pools, blood grouping and compatibility tests are nevertheless not necessary. In using this material or in the administration of group O blood an additional factor of safety is the slow administration so that the active agglutinins are immediately diluted and specifically inactivated by the patient's red cells, body fluids and other tissue cells.

More specifically, a group AB patient suffering from burns will have a relative excess of red blood cells which can readily absorb the agglutinins in the injected plasma, particularly if administered slowly. The advantages of pooled plasma for a case of this sort are obvious. Should additional precautionary measures be desirable, one may add the Witelsky group A and B inhibiting substances to the plasma. Judging, however, from the low incidence of reactions following the use of plasma, there does not seem to be any real indication at the present time for the use of these substances.

If the fatality incidence of burned patients receiving large quantities of plasma is high, this may be attributed to causes other than the administration of plasma.

RECURRENT ERYSIPELAS LIKE ERUPTIONS

To the Editor—At the age of 21 in 1934 a white man, then a college student, was taken suddenly ill with fever (101 F), malaise and headache. Chilly sensations accompanied this picture. This episode occurred in April of that year and began suddenly in the evening. Early the next morning he awoke, feeling worse, but now he noticed a bright red shiny, well outlined area on the tibial surface of his right leg at the junction of the middle and lower thirds. There was a painful right inguinal adenitis but no evidence of varicosities, lymphangitis or thrombophlebitis. There was no antecedent history of an abrasion or infection of the leg. He suffered a mild trichophytosis, but this was not infected and was of the sodden scaly interdigital type. He was put to bed and ointment of ichthammol was applied. Within thirty-six hours his fever had abated and, although somewhat stiff, he was able to walk. Within three days he was feeling well. At the end of the third day all evidence of active inflammation had disappeared and the inguinal glands were no longer palpable. For about two months the area remained red as long as he stood on it and, when elevated, would become a rusty brown. Telangiectatic vessels were seen for a while and occasionally small petechiae were present. Within four months complete resolution had occurred and he experienced no further difficulties. He finished college, completed medical school and was in the third year of his internship when the exact repetition of the episode occurred. The history was identical, both as to time of the year, time of day onset appearance, distribution of the lesion course and recovery period. This time the lesion was treated with continuous hot wet dressings of magnesium sulfate. He recovered in the usual time and was symptom free until March 1, 1943. At this time a sudden onset of chilly sensations, fever and malaise without evidences of coryza or sore throat made him suspicious of a recurrence of the old trouble. Again the course of symptoms, the appearance of the lesion and its distribution, along with the accompanying adenitis, exactly duplicated previous episodes. This time he was treated with sulfadiazine (2 Gm every four hours for three doses then 1 Gm every four hours) and resolution took place in about thirty-six hours, the same as with the previously treated attacks for which heat and ichthammol were used, each with measurable success. In one instance (the second recurrence) a leukocyte count was performed which showed a total of 14,000. No additional laboratory studies have ever been done. This is to me obviously a localized erysipeloid type of cellulitis, but I have never heard of the recurrence of specific symptoms and the recurrence of the lesion in exactly the same location, with the course of the febrile period of thirty-six hours being unaffected by the therapy used. Please comment on this problem as to a specific name or entity, if known, the probable reasons for recurrence in the same locality without evidence of antecedent infection (except the mild epidermophytosis) and any recommendations for either prophylaxis of probable future attacks or for therapy, should another occur.

M.D., Maryland

ANSWER—Cases of this kind are not uncommon. They occur usually on the face or extremities and are often responsible for localized elephantiasis the result of oft repeated attacks. Most of them, if not all, are due to infection with streptococci and they are referred to as recurrent erysipelas or erysipelas-like eruptions. J. L. McGlasson (Recurrent Erysipelas of the Legs with Dermatitis of the Feet, *Arch. Dermat. & Syph.* 14:6/9 [Dec.] 1926) called attention to the frequency with which such cases are associated with dermatitis of the feet. Traub and Tolmach (Erysipelas-like Eruption Complicating Dermatomyofascioma, *THE JOURNAL*, June 26, 1937, p. 2187) reported a series of such cases and because of the association with foot infection stated their belief that they are dermatophytids. Sulzberger, Rosenberg and Goetze (Recurrent Erysipelas-like Manifestations of the Legs, *ibid.*, p. 2189) reported some experimental research in such cases and concluded that at least some of them are dermatophytids, eruptions caused by fungi. This conclusion is not accepted by most dermatologists. Goeckerman and Wilhelm (Recurrent Lymphangitis, *California & West Med.* 55:251 [Nov.] 1941) adhere to the general belief that they are of streptococcal origin and report that they found streptococci in the tissues just as in erysipelas but that the process is a deeper one than true erysipelas and therefore should be called lymphangitis.

The rate of recurrence varies widely, some persons having attacks every week or two, others being fortunate enough to have their recurrences at long intervals. Cases are recorded in which there have been thirty attacks during a period of years. Most of them are mild with little or no fever, but the disease may at any time become severe. Delbanco and Callomen (*Handb. d. Haut u. Geschlkr.* 9/1, p. 17, 1929) cite the case of Hertz and Vidal in which after many mild attacks a severe one, even endangering the life of the patient, occurred. Goeckerman and Wilhelm observed a case which at first was confined to the legs, then after some years of recurrence the hands also became involved and then the attacks were accompanied by a wide spread, almost generalized, oozing, crusting, fissuring and scaling dermatitis which cleared up promptly as the local process resolved after each attack.

The infection takes place through atrioms furnished by other disease or trauma, on the feet often through the openings caused by the disease usually ascribed to ringworm infection, on the hands sometimes secondary to other forms of dermatitis, as the case of McGlasson consequent to procaine dermatitis, and on the face usually through small breaks in the skin or mucous membranes of the nose or mouth.

To explain the recurrence limited to a particular site even though plenty of atrioms are present through which other sites

can be infected, it seems necessary to assume that the infection remains latent over long periods, flaring up when local resistance is lowered. Goeckerman and Wilhelm explain this as follows: 'A change in the patient's immunity has taken place, confining the activity of germs to a restricted area of the lymphatic bed and from there they act much like a focus of infection in the tonsils or teeth.'

In our observation acute exacerbations are usually brought about by trauma, exposure, overwork, exhaustion or improper hygiene. Others have reported that recurrences seem to be prevented by attention to the prevention of the openings in the skin through which infections may take place. This does not agree with the theory of recurrence but it may be that attention to the local skin condition was accompanied by care to prevent other causes of lowered resistance. Roentgen rays and ultraviolet light are beneficial to true crypts and may be found of value in preventing the recurrences of the lymphangitis under discussion. The same physical measures may be tried in the effort to hasten the resolution of the attacks if others occur but it is doubtful whether any therapy can shorten the record already set.

TECHNIC OF AURAMINE STAIN FOR TUBERCLE BACILLI

To the Editor—Will you please send me the formula and directions for using the auramine stain for tuberculosis?

Clifford W. Atherton M.D. Farmington, Ill.

ANSWER—O. W. Richards, E. K. Kline and R. C. Leach (*Am Rev Tuberc* 44:255 [Sept] 1941) of the Spencer Lens Company use a monocular microscope with light rich in ultraviolet rays passed through a blue ultraviolet transmitting filter, reflected through the microscope from an aluminum surfaced mirror and finally passed through a yellow contrast filter placed in the eyepiece. Smears should preferably be made with fresh sputum. Procedure: 1. Make direct smears of sputum or of sputum concentrate on glass slides and fix by heat in the usual manner. 2. Stain for two to three minutes with a solution of 0.3 per cent auramine in 3 per cent phenol (carbolic acid) solution at room temperature. 3. Wash with water. 4. Decolorize with a solution of 0.5 per cent concentrated hydrochloric acid and 0.5 per cent sodium chloride in 70 per cent alcohol for one minute, pour off and add fresh decolorizer for two additional minutes. 5. Rinse, dry and examine. Almost any concentration of auramine will give the desired result, as little as 0.05 per cent of dye may be used. The concentration of phenol may also be reduced. Satisfactory results have been obtained with 0.5 per cent auramine in 2 per cent phenol. The auramine is dissolved with gentle heat but the stain becomes cloudy on cooling. Cloudy solutions are just as satisfactory as clear ones but they should be shaken just before using. The stain after a number of weeks gradually loses some of its fluorescent properties. Smears of known positive sputums should be used as check on the dye. Emil Bogen (*ibid* p. 267) says that a simple mercury vapor lamp or high powered filament bulb may suffice and uses an ordinary bacteriologic microscope. The thinly smeared sputum slides are stained by any acid fast staining technic except that the carbol-fuchsin is replaced by auramine. One gram of pure auramine powder is placed in a flask, one gradually adds 1,000 cc of distilled water shaking vigorously until it is completely dissolved and then adds 50 cc of pure liquefied phenol and again shakes the flask. A temporary clouding later settles out, leaving a clear yellow solution which keeps a long time in the dark. The Hermann procedure is followed at Olive View Sanatorium: 1. Fix with heat. 2. Flood with auramine solution and steam five minutes. 3. Wash in running water. 4. Decolorize in 70 per cent alcohol containing 3 per cent hydrochloric acid until the preparation is colorless. 5. Wash in running water. 6. Dip in a 0.1 per cent aqueous solution of potassium permanganate (this solution remains usable for about a week after turning brown). 7. Wash in running water. 8. Dip in Loeffler's alkaline methylene blue solution. 9. Wash in running water. 10. Dry and examine with the fluorescence microscope. The Chicago Branch Laboratory of the Illinois State Health Department (Lind H. E. and Shaughnessy H. J. *J Lab & Clin Med* 27:531 [Jan] 1942) use (1) a monocular microscope, (2) an 8 mm objective and a 20× ocular or a 18 mm objective and a 6× ocular, (3) a low voltage high amperage light source such as a Universal microscope lamp of 65 volts and 275 amperes with clear bulb and transformer (numbers 351 and 353 lamps are suitable), (4) a blue ultraviolet transmitting filter in front of the light source, (5) an aluminum surfaced mirror in front of the microscope mirror and (6) a yellow filter placed in the ocular (this is a complementary filter necessary to see the acid fast bacteria which fluoresce to appear yellow). The staining solution is composed of 0.1 Gm of auramine O (National Aniline Com-

pany) 3 cc of liquefied phenol and 97 cc of distilled water. The decolorizing solution is 100 cc of 70 per cent alcohol, 0.5 cc of concentrated hydrochloric acid and 0.5 Gm of sodium chloride. There is no counterstain. Smears are made as usual and fixed by heat. Auramine is applied for two minutes, washed and decolorized with acid alcohol for two to four minutes and then redecolorized in a fresh solution of acid alcohol at least two minutes and again washed and dried. Individual staining is preferred. There is no danger of overdecolorizing, but there is trouble when decolorization is insufficient. The acid fast bacilli appear as small bright yellow bacilli against a dark background.

EFFECTS OF BLOOD TRANSFUSION ON BONE MARROW

To the Editor—Does a single blood transfusion have any effect on the bone marrow of the recipient? Do repeated transfusions have any effect on the bone marrow of the recipient? Do repeated small transfusions have any effect on the bone marrow of the recipient? If the production of red cells in the bone marrow as stated is either stimulated or depressed are there any exceptions?

M. D. Connecticut

ANSWER—In animal experiments it has been found that bleedings stimulate erythropoiesis while transfusions depress it and it would appear that the same holds true in man. The reason for this is that the most important factor in erythropoiesis is the oxygen tension of the bone marrow, low tensions having a stimulating effect while high tensions have a depressing effect. For example, Runkhard, Moore, Dubach and Wade (*Effect of Breathing 80 to 100 per cent Oxygen on the Erythrocyte Equilibrium in Patients with Sickle Cell Anemia*, *abstr THE JOURNAL*, April 10 1943 p. 1245) found that in patients with active sickle cell anemia with pronounced reticulocytosis the breathing of 80 to 100 per cent oxygen caused the reticulocyte count to drop from 20 to 30 per cent to as low as 1 per cent and there was a concomitant drop in the erythrocyte count. When the oxygen was discontinued the reticulocytes reappeared accompanied by a shower of normoblasts and a rise in the red cell count.

A contrasting example is the polycythemia of mountain sickness. An exception to the depressing effect of blood transfusion on the bone marrow is seen in pernicious anemia in which transfusions were often observed in the past to bring about remissions in the disease. This however, should not be attributed to the action of the blood per se but rather to its function as a vehicle by virtue of which blood transfusion may serve also to transfer vitamins, hormones and other factors active in minute amounts. Obviously the vitamin or hormone itself if available would be much more effective than a blood transfusion in such cases and in fact, liver has displaced blood transfusion in the therapy of pernicious anemia except in severe untreated cases in which blood transfusions are still of value to tide the patient over until the liver therapy takes effect (Werner A. S. *Blood Groups and Blood Transfusion* ed. 3, Springfield Illinois and Baltimore Charles C Thomas 1943 pp. 77 and 85).

TRANSVERSE VERSUS VERTICAL ABDOMINAL INCISION

To the Editor—How does the transverse abdominal transection of the rectum (W. Meyer) compare with the usual vertical incisions in frequency of postoperative herniation or other complications and sequelae (adhesions, paralytic ileus and so on)?

Isadore I. Rosen, Captain M. C. A. U. S.

ANSWER—Although the transverse abdominal incision has not become popular those who employ it are unanimous as to certain of its advantages. Sectioning of one or both rectus muscles has no serious anatomic or physiologic sequelae. The muscle when healed simply presents an extratendinous intersection. Cleavage lines in the abdominal wall assume a generally transverse direction. It is argued that any incision that parallels the fleshy and aponeurotic fibers will be the one that causes the least structural and physiologic damage. Good examples of such incisions in the lower part of the abdomen are the McBurney and the Pfannenstiel modified by Maylard. The transverse incision in the upper part of the abdomen is least likely to cause injury to the intercostal nerves which supply the abdominal parietes. A vertical incision that passes through or laterally to the rectus muscle will denervate whatever tissue lies medially to that. This frequently results in atrophy of the muscle. Sloan has estimated that the lateral pull of the flat abdominal muscles, the external oblique, the internal oblique and the transversalis is between 30 and 50 pounds. With a vertical incision this energy would be applied to the wound disruption whereas with a transverse incision the muscle pull aids in closing the incision. The nerves cut across in a vertical incision are hyperirritable in the early postoperative period. In a subconscious effort to minimize pain the patient splints his abdomen thus restricting the diaphragmatic excursion which in turn leads to decreased vital capacity, anoxia and pulmonary

atelectasis. Mansfield and Lich employed the transverse incision in both the upper and the lower part of the abdomen for a period of one and one-half years. They did not have a single instance of postoperative hernia or even of weakening of the abdominal wall in spite of the fact that in several of their patients the wound was the seat of a rather severe infection with prolonged healing. Hunter did not have a single wound disruption or postoperative hernia in 570 gynecologic operations in which a lower transverse abdominal incision was employed. While no definite report on the subject is to be found in the literature, the consensus as to the occurrence of postoperative adhesions after these incisions is that it is much less frequent than with the longitudinal incisions. Storm believes that this is due to the fact that the nerve supply of the abdominal wall remains intact. If this is true the occurrence of postoperative ileus should also be a rare complication.

FULMINATING MENINGOCOCCIC MENINGITIS (WATERHOUSE-FRIDERICHSEN SYNDROME) WITH ADRENAL GLAND HEMORRHAGE

To the Editor—Is there any explanation for the occurrence of hemorrhage into the adrenal glands in cases of Waterhouse-Friderichsen syndrome? Why should these structures, rather than other parts of the body, be the site of hemorrhage?

Lieutenant Colonel, M. C., A. U. S.

ANSWER—The Waterhouse-Friderichsen syndrome by definition (Dorland's American Illustrated Medical Dictionary) refers to the fulminating or apoplectic form of meningococcic cerebrospinal meningitis in which death occurs within a few hours and meningeal symptoms have scarcely had time to develop or, commencing, are cut short by simultaneous meningococcus invasion of the medulla of the adrenal glands with hemorrhages. Meningococci are in the blood stream and hemorrhages occur in many tissues of the body as well as in the adrenal glands. Extensive spontaneous hemorrhages into one or both adrenal glands without adequate explanation occur not infrequently in newborn infants; they are much less frequent in adults. In some of those cases in adults, not associated with meningococcic infection, bacteria have been demonstrated in the capillaries and hemorrhagic tissues of the adrenal glands. The hemorrhages in the adrenal glands in patients with meningococcic or other bacterial septicemia apparently result from the local effects of the bacteria in the tissues. The hemorrhagic destruction of adrenal gland tissues vital to the host is probably much more serious than the coincident hemorrhages in less vital tissues elsewhere in the body. There may be, however, some dispute in ascribing the cause of death to the septicemia or to the extensive hemorrhagic destruction of the adrenal glands. The former probably is the *causa propria* and the latter the *causa proxima*.

DIETHYLSTILBESTROL FOR SURGICALLY CASTRATED PATIENT

To the Editor—A married woman aged 24 had a bilateral oophorectomy for dermoids in 1939. The uterus was not removed. For the past two years she has been taking oral diethylstilbestrol (15 to 3 mg daily) for control of menopausal symptoms. Every six to ten weeks she has been directed to discontinue therapy for several days to allow uterine bleeding. On resuming treatment she usually experiences nausea with occasional vomiting and diarrhea. Is it necessary to continue periodic uterine bleeding? If so, why, and how frequently? Will a hysterectomy eventually be necessary? Are liver function tests or other procedures to determine toxicity advisable in a case such as this which will require estrogenic therapy for many years?

M. D. California

ANSWER—For a patient surgically castrated, estrogens are primarily intended to relieve the symptoms of the menopause. There is little use in producing cyclic bleeding except when such patients are anxious to have menses for psychologic reasons. The dose of estrogens should be lowered to the minimal amount which will afford relief of the subjective symptoms and there will be little likelihood of inducing uterine bleeding. The bleeding resulting from estrogen administration is not harmful as long as it is not excessive in amount and a hysterectomy is inadvisable. The average dose of diethylstilbestrol is 0.5 to 1 mg daily.

The nausea and other gastrointestinal reactions obtained with diethylstilbestrol therapy are not indications of irritation or damage to tissues such as the liver. These side reactions are now considered to be systemic in origin as the result of rapid absorption into the blood stream. When the absorption is delayed, as with the use of diethylstilbestrol dipropionate or dipalmitate, there is a lowered incidence of side reactions. Decreasing the dose of the estrogen will also lessen the incidence of unpleasant reactions (Freed, S. C., Eism, W. M., and Greenhill, J. P. The Therapeutic Use of Diethylstilbestrol Esters, *The Journal*, Aug. 22, 1942, p. 1412).

CARE OF PERMANENT ILEOSTOMY

To the Editor—There was a question concerning the care of colostomy and an answer in *Queries and Minor Notes* (*The Journal*, Sept. 14, 1940, p. 953) but I have been unable to find information concerning the care of permanent ileostomy which presents the problems of a movement of continuous and watery drainage and of a constantly raw and irritated skin around the opening. Is it possible to use any type of plug which may be inserted into the opening and which may be removed periodically? Also are there any new types of cups which protect the skin? Is aluminum powder the best thing to protect the skin? Should the diet be the same as with colostomy patients? Are enemas indicated?

F. L. Neely, M.D., New York

ANSWER—A permanent ileostomy should not be treated by using enemas. It should be protected by the use of a cup which has an opening just large enough to let the ileostomy protrude into it so that it can collect the liquid material in a bag which can be evacuated once a day. Such a bag should be united to the skin by a rubber plastic which will hold the bag firmly in place and protect the skin. If the skin edges become irritated, aluminum powder is excellent. If they become raw and excoriated, the patient should lie on his stomach in bed on a split mattress for a couple of days so that the ileostomy may leak directly into a basin. This will allow the skin to become normal again and then it can be treated by aluminum powder and by the kind of cup indicated.

VIABILITY OF SPERMATOZOA AFTER ENCEPHALITIS

To the Editor—Some time ago a young man had an attack of acute epidemic encephalitis. Recently he had a fresh specimen of semen examined to determine fertility. There were few spermatozoa and those present were nonmotile. Would such a condition be likely to follow an attack of encephalitis? No venereal history or other infection was admitted to account for the condition.

M. D., Illinois

ANSWER—As far as is known at present an attack of acute epidemic encephalitis would not have an effect on the viability of spermatozoa. As long as a few spermatozoa were present, even though nonmotile, the chances are that subsequent examination may reveal motility and greater numbers. If the oligospermia with absent motility persists, the use of gonadotropic substances might be of benefit.

INCIDENCE OF GOITER SINCE INSTITUTION OF IODINE PROPHYLAXIS

To the Editor—Will you please tell me, if possible, where I can get the following information: Where is goiter most prevalent of present in the United States? Has there been a decrease or increase in the incidence of goiter since the discovery of thyroxin by Kendall, Dec. 25, 1914?

P. H. Owens, M.D., Kansas City, Mo.

ANSWER—Good statistics have not been published on the incidence of goiter throughout the country since iodine has been used extensively for prophylaxis. There is no doubt, however, that the incidence of nontoxic goiter has been greatly reduced since iodine has been used for this purpose. It has, of course, dropped since Kendall's discovery of thyroxin in 1914. However, the incidence of toxic goiter has been but little affected by the prophylactic use of iodine.

ODOR ASSOCIATED WITH ADVANCED CANCER

To the Editor—In *Queries and Minor Notes* in *The Journal* May 13, 1943 I read the note from Dr. Morton L. Levin, Albany, N. Y., with regard to odor associated with advanced cancer. In the Jefferson Davis Hospital at Houston, Texas, we have found an additional medicament that will control the odor, especially the odor from advanced carcinoma of the cervix. The treatment is reasonable in cost and easy to apply. The mixture is made up in tablet form. The tablets contain equal parts of dextrose and lactose, boric acid and tartaric acid to make a pill of 29, and organic iodide (5-7 diiodo-8-hydroxyquinoline). The iodine also helps to control the odor. Two to four tablets placed within the vagina two or three times a day control the odor well. This acidulated dextrose lactose iodine mixture eliminates the secondary infection which is in most cases the cause of the odor and often greatly relieves the pain.

CARCINOMA OF THE PROSTATE

A STUDY OF THE PERCENTAGE OF CASES SUITABLE
FOR THE RADICAL OPERATION

J. A. CAMPBELL COLSTON, M.D.
BALTIMORE

In an editorial¹ published in THE JOURNAL in July 1942 I was quoted—and quoted correctly—as stating that of all cases diagnosed as carcinoma of the prostate in the Brady Urological Institute the radical operation was carried out in approximately 5 per cent. This question was raised in a discussion at a meeting of the New England branch of the American Urological Association, and without any available figures in a desire to be conservative, I gave my impression that about 5 per cent of all cases of carcinoma of the prostate seen in any clinic would be found suitable for the radical operation.

The publication of the aforementioned editorial and particularly my statement, which was given purely as an impression and without the background of any statistical data led me to make a study with as thorough a follow-up as possible to determine the end results of all cases in which the radical operation for carcinoma of the prostate was done in the Brady Urological Institute between Sept 1, 1937 and Sept 1, 1942. In this five year period a diagnosis of carcinoma of the prostate was made in 358 cases, of which 318 were admitted to the hospital. During this period 73 radical operations were performed by members of the visiting and house staffs. Thus the radical operation was carried out in 20.2 per cent of all cases seen and in 22.7 per cent of all hospital admissions with a diagnosis of carcinoma of the prostate (table 1).

These figures were so significant that it was deemed advisable to present them to the medical profession. I realize that this percentage of cases suitable for the radical operation is probably higher than would be seen in other clinics, but it can be explained by the fact that many patients are referred to this clinic with a diagnosis of early carcinoma for the express purpose of undergoing the radical operation.

In a similar series studied over a period of two years at the University of Virginia Hospital Vest and Prince³ made a diagnosis of carcinoma of the prostate in 77 cases. Of these, 7 cases or 9 per cent were

considered suitable for the radical operation with a good prognosis for complete cure.

The criteria for cases suitable for the radical operation have been previously stated and depend largely on careful rectal examination.⁴ The malignant growth should not extend beyond the capsule of the gland, into the membranous urethra or beyond the base of the seminal vesicles and of course metastases must not be demonstrable either on physical or on roentgenologic examination. In addition, the serum acid and basic phosphatase must be within normal limits, since the important researches of Huggins and his collaborators⁵ and the Gutmans⁶ have shown that an elevated acid phosphatase level in the blood serum should be interpreted as indicative of metastases from prostatic carcinoma unless some other definite cause for this elevation can be proved. Furthermore no patient should be subjected to the radical operation unless the general physical condition is satisfactory and the patient should have a fair span of life expectancy. Generally speaking carcinoma of the prostate, especially in older persons is a slowly progressive disease, and in every case in which the criteria for operability are satisfactory the question of life expectancy of the particular person must be carefully considered before operation is advised.

These criteria are not absolute, and in some cases radical operation has been carried out on persons in whom it seemed doubtful from the observations on rectal examination that a complete cure might be expected. George Gilbert Smith⁷ some years ago advocated the radical operation in cases in which it was obvious that the whole malignant growth could not be removed but he felt that even though some of the neoplasm might remain, usually in the region of the tips of the seminal vesicles, the patient's subsequent course was much more satisfactory than with any other method of treatment. The removal of the main mass of malignant disease around the neck of the bladder gave permanent relief of obstructive symptoms and effects and in many cases the portion of the tumor which could not be removed, lying as it did well above the neck of the bladder between it and the rectal wall

might grow very slowly and not cause symptoms from its encroachment on either the bladder or the rectum. The following case illustrates this point very graphically.

REPORT OF CASE

D. D. McM., aged 51, seen in June 1924, complained of burning on urination, frequency and blood in the urine. The general physical examination was essentially normal, except for mild

TABLE 1—Percentage of Cases Suitable for Radical Operation Among All Cases Diagnosed as Carcinoma of the Prostate from Sept 1 1937 Through Aug 31, 1942

	Number of Patients	Number of Radical Operations	Per Cent
Diagnosis carcinoma of prostate	158	73	20.2
Admissions to hospital	118	73	22.7

hypertension. On rectal examination the prostate was slightly broader and undoubtedly firmer than normal, and in the right lobe there was an elevated, stony hard, fixed nodule and the induration extended up toward the base on the right side but apparently not into the seminal vesicle. X-ray examinations of the lumbar vertebrae, sacrum and bones of the pelvis were negative for metastases. Since the growth seemed to be entirely within the capsule of the prostate and had not extended into the membranous urethra or into the seminal vesicles, the case was considered suitable for radical operation. This procedure was carried out on July 2. The postoperative course was uneventful, except for a transient epididymitis. The patient was discharged on August 5, the perineal wound well healed, voiding freely without obstruction, with perfect control, able to retain urine throughout the night without arising and voiding every three hours during the day. He was seen at intervals following the operation and remained in excellent general condition with a perfect functional result. In June 1927, three years after the operation, an indurated area was noted high up between the rectum and the posterior wall of the bladder. In subsequent check-up examinations it was observed that this area grew very slowly and that the induration became gradually more pronounced. At the last examination, carried out in 1931, it was my impression that a definite recurrence was present. At no time had there been any urinary obstruction or other symptoms, and the functional result remained perfect. X-ray examinations showed no evidence of metastases. His general health had been good except for an attack of acute cholecystitis, for which a cholecystectomy was done in January 1928. He died on March 25, 1939 with a clinical diagnosis of coronary thrombosis. A complete autopsy was carried out by Dr. Nathan B. Friedman, then of the University of Chicago, who sent the indurated retrovesical mass to me for examination. Autopsy showed no evidence of metastases. The prostate was absent. Under the bladder the extremities of the vesicles were fused together in a firm mass 5 by 3 cm., most of which was on the right. On section this mass showed a group of thick walled tubules embedded in scar tissue. One region showed dilated cystic spaces up to 1 cm., each with reddish and yellow contents. Microscopic examination revealed the right seminal vesicle thickened and fibrotic with hyaline and mucoid interstitial changes and vascular sclerosis. The epithelium of the vesicle was relatively normal, although atrophic and desquamated in areas. Throughout the stroma and invading the nerves at the edges were numerous well differentiated adenocarcinomatous glandular structures.

It is obvious that the upper portion of the right seminal vesicle was not removed at the time of operation. It was probably invaded by the malignant process at the time of operation, but the neoplasm progressed so slowly that it never caused any functional disability by pressure on contiguous structures, located as it was

between the posterior vesical wall and the rectum, well above the neck of the bladder. This patient lived fifteen years completely free from urinary symptoms and with a perfect functional result, even though viable malignant cells were present behind the bladder wall during all this time.

OPERATIVE MORTALITY

During the period from Sept 1, 1937 to Sept 1, 1942 seventy-three radical operations were performed and there were four hospital deaths. An analysis of these fatalities shows that 3 patients were over 70, and in all of them evidences of varying degrees of arteriosclerotic cardiovascular disease were found. In 2 of them the cause of death was myocardial failure, and in the third a massive hemorrhage from unrecognized gastric ulcers was considered responsible for death, although here again myocardial disease was a contributing factor. The fourth death occurred from what must be considered a technical error in that, owing to a suspected occlusion of the ureter occurring at operation, it was thought necessary to insert a retained ureteral catheter, which was in all probability the source of a fatal staphylococcal bacteremia which developed.

It is an interesting commentary on the supposed danger of the radical operation that during the five year period fifteen such operations have been carried out by the various resident urologists of the Brady clinic without a death. This series, comprising as it does only a five year postoperative follow-up, is in no sense intended as a presentation of the percentage of cures following radical operation. It must be remembered that the study was undertaken primarily to determine the percentage of cases considered suitable for the radical operation from the total number of cases seen in the clinic over a five year period in which a diagnosis of carcinoma of the prostate was made. In this connection Lewis⁸ made a study of the five year end results of the radical operation and found that approximately 50 per cent of the patients subjected to this procedure were alive and well without evidence of recurrence or metastasis more than five years after the operation.

In the present series of 69 patients who left the hospital after the operation, 10 have died from recurrence or metastasis, 11 are known to be alive with metastasis

TABLE 2—Mortality and Immediate Results of Radical Operation for Carcinoma of Prostate (1937-1942)

Living no evidence of recurrence or metastasis	48

or recurrence or both, and 48 are living without evidence of recurrence or metastasis in periods ranging from six months to five years after the operation (table 2).

RELATION OF GOOD PREOPERATIVE PROGNOSIS TO THE ULTIMATE RESULT

As has been previously stated, the preoperative prognosis, as far as the curability of the disease is concerned, is based entirely on careful rectal examination, provided

8 Lewis, L. G. Carcinoma of the Prostate. Young's Radical Prostatectomy. J. Urol. 47: 302-305 (March) 1942.

of course that no evidences of metastases are present, either clinically or roentgenologically. It has been the custom in the Brady Urological Institute for the examiner to state his impression, good or poor, from his observations on rectal examination. The sources of error lie in the extent of the disease, which may be impossible to recognize accurately on rectal palpation, and from the individual interpretation of the examiner. However, with these limitations in mind, from the preoperative examination in the 69 operative cases in which the clinical diagnosis was cancer the prognosis was classed good in 43 and poor in 26. Of the 43 patients with a good prognosis 41 are living and well without evidence of recurrence or metastasis, 1 has died from recurrence or metastasis and 1 has died from heart disease.

Of the 26 patients with cancer the extent of which caused the examiner to call the prognosis poor, 8 are living and well without evidence of recurrence or metastasis, 9 are living with evidence of either recurrence or metastasis, 8 have died from either recurrence or metastasis and 1 has died from other causes (table 3).

From a glance at these figures it is obvious that a good clinical preoperative prognosis is an important factor in the ultimate result, but it is equally evident

TABLE 3—Cases Classified as Good or Poor Prognosis for Ultimate Cure—A Comparison of Results

Preoperative Prognosis	Number of Cases	Living and Well No Evidence of Recurrence or Metastasis	Living and Well with Evidence of Recurrence or Metastasis	Dead Recurrence or Metastasis	Dead Other Causes
Good	43	41	0	1	1
Poor	26	8	9	8	1

that patients classified under a fair or poor prognosis must not all be denied the opportunity for complete eradication of the disease which the radical operation affords, because 8 out of 26 patients with a poor prognosis are living and well without evidence of recurrence or metastasis. The excellent temporary results, often of surprisingly long duration, that may be obtained by eradication of the main mass of malignant disease in cases in which it is evident that complete removal of all the neoplasm is impossible have already been stressed.

FUNCTIONAL RESULTS

There has, unfortunately, been an all too prevalent idea among both the general medical profession and some urologists who are not familiar with the operation that total incontinence of urine is an inevitable result of the radical operation. It might be argued that, even though this were so, it a complete cure of the malignant disease could be obtained a life of complete incontinence would be distinctly preferable to death from prostatic cancer, with its certain disability and suffering (table 4).

Incontinence of urine following the radical operation in many instances at least, must be attributed to the sutures which anastomose the stump of the urethra to the neck of the bladder. The distal stump of the urethra contains the muscles of the external sphincter, and it is easy to understand that these structures may be constricted and their continuity severed by sutures tied directly through them. In 1940 Vest⁹ described

his method of completing the anastomosis, which, briefly, depends on the principle of passing the anastomosing sutures out through the structures of the perineum and tying them there. By this method a snug approximation of the stump of the urethra to the neck of the bladder can be obtained, and no knots are tied directly over the muscles of the external sphincter, so that the suture

Good control	30
Fair control	11
Poor control	8
Total number of cases	49

knot is cushioned by the soft tissues of the perineum. Since the introduction of this principle in the Brady clinic, the functional results have been appreciably improved (table 5).

The patients who survived operation and left the hospital have been classified with regard to urinary function as good, fair and poor. Under the first heading are classed those patients who are able to void freely without difficulty or obstruction or undue frequency and in whom urinary control has been retained to such a degree that no apparatus is necessary either day or night. Under fair are classified those patients who have good control at night but when up and about dribble small amounts of urine at times so that an apparatus is necessary at least part of the time. These patients are able to void freely without obstruction and the functional result is excellent except for the inability at times to control small amounts of urine. Under poor are classified those patients who have little or no control and require some form of apparatus both day and night. A good functional result can almost invariably be expected in the younger age group.

MISTAKES IN DIAGNOSIS

The operative specimen in 5 cases on microscopic examination failed to reveal evidences of malignant disease. In 3 of these cases fibrosclerotic areas which occurred in the posterior capsule were mistaken clinically

TABLE 5—Urinary Control Since 1940 Since When the Modified Suture Technic Has Been Used in All Cases

Control good	30
Control fair	4
Control poor	3
Total number of cases	37

cally for malignant disease. All these patients had varying degrees of urinary obstruction and all recovered from the operation with a good functional result. In 1 case microscopic study showed that a large area of intarction had occurred in the prostate which clinically was considered to be carcinoma. In the fifth case microscopic sections of the operative specimen showed tuberculosis which had been mistaken clinically for malignant disease. This patient had symptoms of urinary obstruction, there were no other evidences of tuberculosis of the urinary tract and, following operation, healing was uneventful with an excellent functional result.

⁹ Vest, S. V. Radical Perineal Prostatectomy. Modification of Closure Surg. Gynec. & Obst. 70: 935-937 (May) 1940.

It should be an invariable rule that the clinical diagnosis should be confirmed at the operating table by a frozen section of the suspected area. This procedure is quite simple, and a satisfactory piece can be removed from any portion beneath the posterior capsule with the cautery knife without fear of disseminating malignant cells throughout the wound. The time required to prepare and study the section can be utilized in mobilizing the prostate and exposing it satisfactorily in preparation for the radical operation. If the section proves to be benign, the incision can be rapidly closed, and only a few days hospitalization is necessary, since, of course, the urinary tract is not opened.

The brilliant results which have been obtained by the endocrine control of carcinoma of the prostate, either by orchietomy,¹⁰ introduced by Huggins, or by the administration of female sex hormone,¹¹ have raised the question in some minds whether the radical operation in early cases of this disease is ever justified.

The regression of bony and even pulmonary metastases¹² and the diminution in the size of the local growth, with relief of urinary symptoms even in extensive neoplastic disease are incontestable, and the results in the Brady Urological Institute in the treatment of these cases have fully confirmed the observations of Huggins. However, the ultimate fate of these patients, who may show a remarkable and prompt response to this method of treatment is as yet unknown, since none of these cases have been followed over a sufficiently long period of time to make certain that the regression of the primary growth and metastases are permanent. Decided improvement persisting over varying periods of time up to a year may be followed by a gradual return of the symptoms and evidences of activity of the disease, which cannot be controlled by further treatment with the female sex hormone.

Randall¹³ has recently reported 5 cases of extensive carcinoma of the prostate in which bilateral orchietomy was done seven, eight and nine years ago. Four of his patients died forty-three days, eight months, seventeen months and three and one-half years respectively after the operation. One is living six and one-half years after the operation, but x-ray examination shows massive metastases of the dorsolumbar spine, which have apparently been ameliorated by the use of diethylstilbestrol. Evidence has not been adduced to prove, therefore, that complete eradication of carcinoma of the prostate can be obtained by endocrine treatment, but the palliative results which are observed in approximately 80 per cent of the cases, even with extensive metastases, must be received without question. Some writers have contended that, on account of the early involvement of the perineural lymphatics,¹⁴ carcinoma of the prostate can never be completely removed by surgical operation. Carcinoma in other locations

throughout the body also has a tendency to invade lymphatics, so that, if this contention was followed to a logical conclusion, an effort to remove a carcinoma anywhere in the body would not be justifiable.

It is the feeling, therefore, in the Brady Urological Institute that any patient with an early carcinoma of the prostate who fulfils the necessary criteria for the radical operation should have the benefit of this procedure. As far as our present knowledge goes, this operation in certain selected cases offers the only possibility for complete eradication of the disease.¹⁵

COMMENT

A study of the radical operations for carcinoma of the prostate performed in the Brady Urological Institute by various operators during the five year period from Sept 1, 1937 to Sept 1, 1942 has been carried out. This study has been undertaken to determine the percentage of cases suitable for the radical operation out of the total number of cases seen in the clinic in which a diagnosis of carcinoma of the prostate was made. The study, of course, in no way attempts to evaluate the five year percentage of cures, but the subsequent course of the patients subjected to the radical operation has been followed as closely as possible, with special reference to recurrence and metastasis and to the functional result.

There were four hospital deaths in the series of seventy-three operations—a mortality of 5.5 per cent. These fatalities have been summarized and analyzed. The importance of a good preoperative prognosis for complete cure of the disease has been emphasized. Of 43 patients for whom the prognosis was good, 41 are living and well without evidence of recurrence or metastasis. Of 26 patients for whom the prognosis was poor, 8 are living and well at intervals varying from three months to five years.

Intensive follow-up of all patients with early cancer of the prostate subjected to Young's radical operation shows that more than 50 per cent are free from recurrence or metastasis from five to twenty-seven years after leaving the hospital. A study of the postoperative functional results has also been carried out on the 69 patients who comprise this series. In 49 the functional result was excellent, all patients having complete urinary control. The result was classified as fair in 11 cases in which there was occasional slight leakage during the day, and in 8 the result was evaluated as poor, as some form of apparatus was necessary during the day and in some instances during the night. It is important to complete the anastomosis between the neck of the bladder and the stump of the urethra by means of sutures introduced so that there will be no strangulation and subsequent necrosis and scarring of the muscles of the external sphincter. It is evident that sutures tied in such a way as to constrict the sphincter muscles must play a large part in the incidence of postoperative incontinence.

Frozen section biopsy, carried out with the patient prepared for the radical operation, is a simple means of avoiding mistakes in diagnosis.

THE DIAGNOSIS AND TREATMENT OF
EARLY CARCINOMA OF THE
PROSTATEROY B. HENLINE, M.D.
NEW YORK

Cancer of the prostate gland, because of its frequent occurrence and silent onset, occupies a prominent place among the serious maladies affecting men past 50 years of age. In the early stages it gives no warning of its presence. Later, when symptoms occur from extension of the disease beyond the prostate, complete surgical removal of the gland will not eradicate the disease.

By "early carcinoma of the prostate gland" I refer to those cases in which the cancer is entirely confined within the boundaries of the prostate. In such cases, when the remainder of the prostate is free from other pathologic abnormalities, there are no symptoms referable to the gland and the patient is unaware of the presence of prostatic disease. He first becomes aware of the growth only when it has spread to distant parts of the body. In most prostatic disorders the patient's attention is likely to be attracted to the disease by frequency of urination, diminished urinary stream or blood in the urine, but all of these symptoms are singularly absent in early, uncomplicated carcinoma of the prostate. The disclosure of a hard nodule in the prostate, on rectal palpation, is the only sign of uncomplicated early prostatic carcinoma.

ETIOLOGY

It has recently been shown by Huggins and his associates¹ that the stimulus causing the dissemination of prostatic carcinoma is an imbalance between the male and female sex hormones. "The activity of this neoplasm is increased by the injection of androgen and is decreased by significantly lowering the androgen level by excision of the testes or by inactivating the androgens by estrogen injection." The quantity of these two hormones produced within the body may be altered at about the age of 50 years. It is well within the realm of possibility that the varying quantities of androgens and estrogens in the body may produce prostatic cancer. Should this be proved, the indiscriminate and prolonged injection of androgens may prove very dangerous.

There is every evidence to suggest that the work by Huggins on these hormones has opened a new field in the search for the cause of cancer. Much evidence is accumulating to verify his findings on the relationship of androgens to prostatic cancer. Biochemistry may thus point the way in the search for the causes of other types of cancer.

THREE TYPES OF PROSTATIC DISEASE

It is necessary to have a clear conception of the normal prostate gland and to recognize the regions where various pathologic lesions may develop. According to Lowsley² the prostate is composed of five separate lobes, consisting of two lateral lobes and an anterior, a posterior and a median lobe. Usually the anterior, posterior and median lobes atrophy at or near birth and, as far as we know, have no function during life, although

their remnants persist and are frequently demonstrable. There remain only the two lateral lobes, which enlarge at puberty and are vitally connected with the sexual function. These two lobes consist of long, branching, functioning glands in which prostatic fluid is formed. They also contain minute glands which extend just under the mucosa, whose exact function is not known. When we speak of the prostate during middle life we refer to these two lateral lobes.

It is generally believed that all prostatic disease develops in the same area and from the same portions of the gland. This is an erroneous assumption. There are three general areas within the prostate which may be involved in a pathologic process and three main types of prostatic disease. It is usual for each type of pathologic change, at least during its inception, to limit itself to a particular area, but any combination of these distinct entities may coexist.

PROSTATIC INFECTION

The two lateral lobes, usually referred to as the functioning prostatic glands, are the seat of prostatic infections. Bacteria may invade the deep recesses of these tortuous glands in the lateral lobes and produce an acute or chronic prostatitis or a prostatic abscess or they may be the seat of endogenous prostatic calculi. According to recent investigations, the functioning portions of these lateral lobes are rarely the site of origin of either prostatic hyperplasia or cancer.

PROSTATIC HYPERPLASIA (SO-CALLED ADENOMA)

It is generally agreed that hyperplasia of the prostate develops just beneath the urethra. Deming and Wolf³ in a recent study of 210 prostates showed that hyperplasia is first seen as a fibromuscular mass in the muscular wall of the prostatic urethra, which lies close to the urethra. These fibromuscular masses lie parallel to the muscular fibers of the urethra between the ducts of the functioning glands and stimulate epithelial hyperplasia from these ducts. These authors state that this hyperplasia is not an enlargement of existing prostatic glands but although similar in structure, is composed of newly formed glandular elements from the ducts of the prostatic glands. This explains its locality surrounding the prostatic urethra, from which the growth extends to compress the functioning glands of the lateral lobes toward the capsule and hence assumes the position of the lateral lobes on each side of the urethra. This hyperplasia may also develop in the median, subcervical or subtrigonal lobe, where nests of glands are present.

CARCINOMA OF THE PROSTATE

Carcinoma develops as a distinct pathologic process in the prostate and is not related to either prostatic infection or hyperplasia. Carcinoma usually develops in the posterior lobe, an area rarely, if ever, affected by either infection or hyperplasia. According to Moore⁴ and Rich⁵ the frequent finding of compressed or atrophic prostatic glands with early carcinoma suggests that such a cancer may develop from, or in conjunction with, such senile atrophic remnants. Although carcinoma of the prostate is predominantly a lesion of the posterior lobe, it may arise in any portion of the gland. Moore states that carcinoma and hyperplasia of the prostate are two distinct lesions and occur inde-

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital.

⁵ Rich, A. R. Frequency of Occurrence of Occult Carcinoma of the Prostate. *J. Urol.* 33: 215 (March) 1934.

pendently, although the two occasionally are found in the same portion of the gland. He further states that, viewed from the point of view of the general problem of invasion and metastases, carcinoma of the prostate exhibits early invasion of the perineural lymphatics within the organ, but metastases and invasion outside the organ is a late manifestation of the disease. This is important clinically, since early complete removal of the entire prostate will eradicate the disease. Complete pathologic examination of adequately removed prostates confirms the fact that diagnosis may be made in certain cases of early carcinoma and the growth completely removed before extension has occurred.

Only when one visualizes the site of origin and mode of progression of infection, hyperplasia and carcinoma of the prostate can one select the proper surgery for their relief. All of these three pathologic processes may develop in the same prostate but, as far as we know, each develops independently.

INCIDENCE OF OCCURRENCE

According to Moore¹ and to Rich,² carcinoma of the prostate develops in approximately 15 per cent of men past 50 years of age. This incidence increases with advancing years. When one considers that one in every seven men past 50 years of age has carcinoma of the prostate, its importance in advancing years becomes apparent. It also becomes obvious that many of these cancers must progress very slowly, otherwise extensive carcinomatosis and death from prostatic malignancy would be an even more frequent finding among elderly men. Such extensions, however, are far too common, and prevention of their occurrence should be our goal. It may be that carcinoma of the prostate actually has become more common, but it is more likely that our awareness of its prevalence, plus improved diagnostic methods and careful search for its presence, accounts for its more frequent recognition.

SITE OF ORIGIN OF CARCINOMA

The most common site of origin of carcinoma of the prostate is the posterior lobe. This lobe is the portion of the gland posterior and posterolateral to the fan shaped ducts which enter the sides of the urethra. The function of this lobe, if any, is unknown, and it remains dormant from birth until senile changes occur. This lobe, together with the functioning prostatic glands, which also undergo atrophic changes at about 50 years of age, forms the false capsule of the prostate, often referred to as the posterior lamella. Most malignant growths occur in this area. On examination of the prostate by rectum, it is this posterior lamella with which the finger comes in contact. The ease with which it may be digitally palpated permits early recognition of any area suggestive of malignancy. Thus the importance of rectal palpation of the prostate during routine examinations becomes apparent.

SYMPTOMS

There are no symptoms of uncomplicated early carcinoma of the prostate. In the absence of other gross prostatic disease, no symptoms are present to call the patient's attention to this malady. Only when extension beyond surgical control has occurred do symptoms develop.

However, it is not uncommon for the prostate to be the site of two or even three distinct pathologic processes. Most other disturbances in the prostate present symptoms referable to this gland and, during examina-

tion, an area suggestive of malignancy may be encountered. Carcinoma may be present in conjunction with prostatic infection, and not infrequently some degree of hyperplasia coexists. The symptoms produced by the infection or hyperplasia cause the patient to seek relief, while the early carcinoma must be suspected from digital palpation alone.

DIAGNOSIS

Detection of the presence of early carcinoma of the prostate devolves on the physician who examines patients periodically for their general health. Without his help, few cases of early carcinoma of the prostate will ever be seen by the urologist. Certainly no general physical examination of a man 50 years of age or over is complete without rectal palpation of the prostate. If routine physical examinations of such patients were undertaken at least once a year, and the prostate palpated each time, many patients with areas suggestive of malignancy would be discovered and further investigation undertaken. For a physician to palpate a suspiciously hard nodule in a prostate and "wait" to see what happens is a violation of the trust placed in him. These are the patients who may be cured of this disease.

Since no symptoms are present in early prostatic malignancy, its presence is first suspected by rectal palpation of the prostate. Although a definite diagnosis cannot thus be made, it is from this group that cases suitable for total prostatectomy must be selected. The statement so often made that when the diagnosis of carcinoma has been made by rectal palpation it is too late for complete surgical removal has been disproved many times. When prostatic malignancy is suspected on rectal examination, perineal exposure of the prostate is warranted in order to confirm the diagnosis.

Carcinoma should be considered likely if an area—no matter how small—which feels definitely harder than the rest of the gland, is found in the prostate. Such an area is often situated to one side of the midline and may feel like a foreign body just inside the capsule of the prostate or between the rectum and the gland. The characteristic rounded feel of the prostate is abruptly broken by the hard area, which, as Smith³ points out, gives the impression of a "square edge." These nodules may be multiple.

Carcinoma may be confused with fibrosis. The age of the patient may tend to relieve one's suspicion of malignancy. Fibrosis frequently is somewhat less hard than malignancy. One may also confuse early malignancy with prostatic calculi. The latter may be located so near the capsule that differentiation by palpation may be impossible. An x-ray examination will aid in making the diagnosis of calculi.

When a suggestive nodule is palpated in the prostate, I advise a perineal exposure to take a direct biopsy of the nodule. A frozen section is made and, if the diagnosis of carcinoma is confirmed, a complete prostatectomy, including removal of the seminal vesicles, is carried out at once. The perineal exposure of the prostate to secure an adequate specimen of the involved area seems to me to offer much more conclusive evidence of the disease than can be obtained by a punch biopsy. A needle passed through the perineum may fail to engage the involved area and a negative report still leaves the surgeon in doubt. A needle biopsy often obtains a tu-

³ Smith, George Gilbert. Total Perineal Prostatectomy of Carcinoma of the Prostate. *J. Urol.* 35: 610 (June) 1936.

scattered cells which necessarily makes the diagnosis uncertain. A direct biopsy of the prostate permits one to ascertain the pattern of the diseased area and thus assures a correct diagnosis.

If an adequate biopsy is obtained through a perineal exposure and the frozen section fails to reveal a malignant growth, the perineum is closed and the patient may be discharged in three to four days. The urethra has not been opened and urination is not disturbed. Two such errors in diagnosis have been made by me within the past three years, but neither patient suffered any ill effects from this procedure. Both had local areas of fibrosis which could not be differentiated from a malignant condition by rectal palpation.

TREATMENT

"Complete prostatectomy" refers to the removal of the entire prostate with its capsule and the entire prostatic urethra. This procedure can be done only by the perineal approach, and such complete removal is necessary to eradicate the disease. The line of cleavage which permits hyperplasia of the prostate to be enucleated suprapubically leaves behind the entire posterior lamella, from which most malignant growths arise. Transurethral resection also removes the hyperplasia, but the so-called capsule, which is the posterior lamella of tissue must of necessity be left behind. Thus, if carcinoma is not found in the tissue removed either by suprapubic prostatectomy or by transurethral resection, there still is no assurance that carcinoma of the prostate is not present. Several such patients have sought relief after each of these operations because of carcinoma of the prostate in the portion of the gland left behind.

Some changes in the technic of Youngs' perineal surgery have improved our results in recent years. The perineal approach to the prostate has been simplified by Belt,⁸ who follows the cleavage plane present between the longitudinal muscle fibers of the rectum and the external sphincter ani muscle, thus almost completely eliminating hemorrhage. It is our custom to remove the capsule of the prostate in almost every case in which perineal prostatectomy is indicated. By doing this we have removed all possibility of the subsequent development of prostatic cancer and may occasionally remove a very early or occult malignancy before a diagnosis is possible. It is not my practice to perform perineal prostatectomy except when specific indications for this approach exist. The distal urethra is completely severed from the apex of the prostate. The prostate is then excised from the vesical neck and the urethra sutured to the bladder neck over a Foley catheter placed through the urethra. The seminal vesicles are removed in carcinoma of the prostate, but in other instances they are cut, tied and left behind. No remnants of prostate are left behind to be the site of future pathologic changes. Bleeding is controlled by sutures in the bladder neck, and only a Penrose drain is left in the perineum for twelve to eighteen hours. Most perineal wounds drain no urine and many heal by first intervention. The catheter is removed about the twelfth postoperative day. I know of the development of no strictures at the vesical orifice following this procedure. Urinary control is rarely a problem

with these patients, but it is not uncommon for a patient to pass a few drops of urine when coughing or on sudden exertion for a few days to weeks. Rectal fistula should be avoided by proper perineal dissection.

REPORT OF CASES

During the past two and one-half years I have had 8 private patients on whom a perineal exposure was undertaken for the diagnosis of early carcinoma of the prostate. One additional patient was subjected to a complete perineal prostatectomy because of definite prostatic infection with fibrosis which did not respond to any palliative treatment, in this patient an early unrecognized carcinoma was discovered by the pathologist. Of these 9 patients, 2 had localized areas of fibrosis and the prostate was exposed by perineum, a biopsy taken and the wound closed with no ill effects. The remaining 7 patients had early carcinoma of the prostate. None of them had evidence of extension outside the prostate or into either seminal vesicle. The following are brief summaries of their histories and pathologic reports.

CASE 1—C T, aged 59 admitted on March 19, 1940, complained of some dysuria and nocturia. Previous examination revealed a hard nodular prostate on the left side and some enlargement on the right. Perineal exposure of the prostate was done on March 20. Frozen section showed adenocarcinoma. A total perineal prostatectomy was done. The temperature was 100.2 F the following day and normal thereafter. The catheter was removed on the twelfth postoperative day. There was no perineal urine at any time. The wound healed and complete urinary control was immediate. The patient was out of bed and ready for discharge but remained in the hospital until the twenty-first postoperative day at his request. The pathologic examination was made by Dr Foote. A frozen section revealed adenocarcinoma of the prostate. The prostate weighed 20 Gm. Scattered nodules consisted of granulomatous tissue and hyperplasia. There was no involvement of the perineural sheaths or seminal vesicles. At present the urine is normal; there are no symptoms. Rectal palpation gives no evidence of recurrence.

CASE 2—Dr C G, aged 68 admitted on Sept 29, 1940, complained of occasional nocturia, but his local physician had discovered a hard nodule in his prostate. Perineal exposure of the prostate was done on October 2. Frozen section showed typical adenocarcinoma. Total prostatectomy was done. The temperature rose to 101 F after operation, gradually returning to normal in five days. The catheter became plugged on the sixth postoperative day and was changed. It was removed on the fifteenth postoperative day but some perineal urinary leakage required its reinsertion. It was finally removed on the twenty-third postoperative day, with the wound healed. The patient was ready for discharge but remained in the hospital until the thirty-first postoperative day. Urinary control was complete when he was discharged. Pathologic examination was made by Dr Foote. A frozen section revealed typical adenocarcinoma of the prostate. Routine examination revealed adenomatoid hyperplasia. "Only here and there are there areas where there is a slight metaplasia and piling up of epithelium. It is probable that the biopsy removed the entire malignant growth." The diagnosis was small and early carcinoma of the prostate. At present there are no symptoms; the urine is normal; there is no evidence of recurrence (figs 1 and 2).

CASE 3—W B, aged 62 admitted on March 23, 1941 did not complain of any symptoms but routine examination revealed a hard nodule in his prostate. His father had died of carcinoma of the prostate. Perineal exposure of the prostate was done on March 26. Frozen section showed carcinoma of the prostate. A total prostatectomy was done. The temperature rose to 102.2 F the following day and returned to normal on the third day. The catheter was removed on the twelfth day with a slight amount of urine draining through the perineum when voiding. There was no perineal urine after the twentieth day,

and control of urine was good. He was discharged on the twenty-third day. Pathologic examination was made by Dr Foote. It revealed adenocarcinoma of the prostate, retention cyst of the prostate, fibrosis of the seminal vesicles and no extension beyond the prostate. At present there are no symptoms, urine is normal and there is no evidence of recurrence.

Fig. 1—Frozen section from case 2 showing typical carcinoma of the prostate.

CASE 4—H W, aged 60, admitted on Oct 26, 1941, did not complain of any symptoms, but routine examination had revealed a hard nodule in the prostate. Perineal exposure of the prostate was done on October 29. Frozen section showed adenocarcinoma of the prostate. Total prostatectomy was done. The temperature rose to 100 F the following day and then remained normal. The catheter was removed on the tenth day. The wound healed and urinary control was complete. The patient was discharged on the twelfth postoperative day. The pathologic examination was made by Dr Foote and Dr Cannon. The prostate weighed 347 Gm. Adenocarcinoma was limited to the posterior lobe. There was no invasion of the capsule or of fat tissue around the prostate and no lymphatic invasion. The seminal vesicles were normal. At present there are no symptoms. Urine is normal. There is no evidence of recurrence (fig 3).

CASE 5—Dr A M, aged 69, admitted on Dec 26, 1941, complained of frequency and pronounced discomfort in the prostatic region after urinating. He had had a transurethral

Fig. 2—Section of excised prostate in case 2 showing only hyperplasia with no evidence of carcinoma.

resection three months previously, with no relief, and requested complete prostatectomy. A total perineal prostatectomy was done on December 29 for fibrosis and infection in the prostate, which had not responded to other treatment. The temperature rose to 99 F on the day after operation and then remained normal. The catheter was removed on the tenth postoperative day, followed by some urinary drainage through the perineum. The catheter was reinserted and removed on the seventeenth

postoperative day, with the wound healed and control complete. Pain persisted, requiring morphine. The patient remained in the hospital until the thirty-third postoperative day, at his request. Pathologic examination by Dr Mider revealed fibrosis with infection. One small area contained an unsuspected malignant growth. At present, perineal discomfort persists, the urine is usually clear with normal control but owing to recurring pyelonephritis it occasionally contains gross infection, there is no evidence of local recurrence (fig 4).

CASE 6—C S, aged 58, admitted on Aug 6, 1942, did not complain of any symptoms, but routine examination revealed a hard nodule in the prostate. Perineal exposure of the prostate was done on August 10. Frozen section showed adenocarcinoma. A total prostatectomy was done. The temperature rose to 101 F and returned to normal on the third postoperative day. The catheter was removed on the ninth postoperative day with the wound healed, and control was good except when he was coughing or on sudden exertion. He was ready for discharge on the eleventh postoperative day but remained in the hospital for other investigation until the sixteenth day. Pathologic examination by Dr Mider revealed adenocarcinoma of the prostate. There was no infiltration of the capsule and no carcinoma around the nerves or blood vessels. The seminal vesicles were normal. At present there are no symptoms and the urine is clear (figs 5 and 6).

CASE 7—J R, aged 59, admitted on Sept 15, 1942, did not complain of any symptoms, but a hard nodule was palpated in

Fig. 3—Carcinoma of the prostate from case 4 showing the typical small irregular acini closely grouped together. The epithelium of the longer acini is high and irregular. Capsule and seminal vesicle showed no invasion of malignant growth.

his prostate. Perineal exposure of the prostate was done on September 16. A frozen section revealed adenocarcinoma. A total prostatectomy was done. The temperature rose to 100 F for one day and then became normal. The patient is still in the hospital, but no urine passes through the perineum. Pathologic examination revealed a wildly growing adenocarcinoma of the prostate with normal seminal vesicles, perineural invasion was present within the gland, but there was no extension outside the capsule.

COMMENT

I am presenting these 7 cases with the full realization that the time which has elapsed since operation is much too short to justify evaluation of the end results. However, evidence is presented to indicate that total prostatectomy may be done with little shock to the patient and with good functional results. From the pathologic reports of the specimens removed there is evidence that the carcinoma was completely removed in each case. In 1 instance (case 2) the report that "the biopsy probably removed the entire malignant growth" makes the likelihood of metastases beyond the prostate unlikely. In no instance were the perineural sheaths, lymphatic vessels or seminal vesicles involved.

It appears likely that carcinoma of the prostate may remain relatively dormant for many months without spreading beyond the confines of the prostate. Three of these patients (2, 4 and 6) had been told that they had a hard nodule in the prostate at least six months before surgical intervention. This confirms Moore's statement that invasion of the vesicles and distant lymphatics is a late manifestation. However, it should not be inferred that one should "wait" to see what happens to a hard nodule in the prostate, since such delay may destroy the patient's chance of being cured.

The problem of exposure of the prostate may seem difficult. Careful dissection is necessary to avoid accidents but we experience less difficulty in teaching our residents to do good perineal surgery than many other procedures. Even if the procedure appears difficult, this should only stimulate us to greater proficiency; it this operation offers the patient a prolonged life expectancy.

More patients with early carcinoma of the prostate have been seen in recent years. Doctors have learned to recognize early prostatic cancer, yet the percentage of operable cases is still pitifully small. When one suspects malignant growth one should advise biopsy through a perineal exposure. If one's own urologist

Fig 4—From case 3 showing the area of carcinoma. The acini are small and irregular and the cells small and hyperchromatic. Areas of chronic prostatitis also are seen.

has failed to equip himself to do this procedure, one should find another who can. A negative punch biopsy is worse than nothing, since it gives one a sense of false security. There will never be a more grateful patient than the one who realizes that his physician has been aware of an early manifestation of cancer and has sought intelligent investigation and treatment to eradicate it before it was too late.

CONCLUSIONS

1 It is necessary to have a clear conception of the region in the prostate from which carcinoma usually develops in order to treat these patients properly.

(a) Infection and calculi develop in the functioning prostatic glands.

(b) Hyperplasia develops near the prostatic urethra (not from the functioning glands) and compresses the functioning glands toward the capsule.

(c) These compressed atrophic gland remnants, together with the dormant glands of the posterior lobe, form the posterior lamella from which about 75 per cent of carcinoma develops. Any combination of these three distinct pathologic entities may be present in the same prostate.

2 Cancer of the prostate has been found in approximately 1 out of every 7 men past 50 years of age.

3 There are no symptoms of early cancer of the prostate, and no symptoms are present unless the prostate is the seat of another pathologic process.

Fig 5—From case 6 showing high power magnification of area of carcinoma.

4 Early carcinoma of the prostate may be suspected by rectal palpation of a hard nodule near the presenting surface of the prostate. Diagnosis is preferably made by biopsy and frozen section taken through a perineal exposure of the prostate.

5 Total perineal prostatectomy is a rational procedure and offers the only hope of completely eradicating this disease. The shock from this procedure should be no greater and often is less than from other forms of surgery on the prostate. Following proper surgical technique the functional results should equal those of any other type of prostatic surgery.

6 Pathologic examination of the specimens removed in these 7 cases failed to reveal any extension of the cancer into the perineural sheaths, lymph vessels or seminal vesicles. Many such lesions must be slow to metastasize.

Fig 6—From case 6 showing the seminal vesicle with no evidence of invasion by carcinoma.

7 A careful digital palpation of the prostate should be a part of the physical examination of every man past 50 years of age. The finding of early lesions in the prostate suggestive of malignancy rests with the physician, and the urologist should prepare himself to investigate and treat these patients intelligently.

THE TREATMENT OF BENIGN
PROSTATIC HYPERPLASIA

IN RELATION TO PROSTATIC CARCINOMA

LAURENCE F. GREENE, M.D.

Fellow in Urology, Mayo Foundation
AND

GERSHOM J. THOMPSON, M.D.

ROCHESTER, MINN.

Amidst the lively controversy concerning the surgical treatment of benign prostatic hyperplasia it is imperative for the general practitioner as well as the urologist to keep the purpose of the operation clearly in mind. Stated simply, surgical treatment is undertaken in an effort to relieve the symptoms of urinary obstruction, so that micturition can again be normal. The restoration of normal micturition is the common goal of suprapubic, perineal and transurethral prostatectomy. In an attempt to reach this common goal, each operation is designed to remove the same hyperplastic prostatic tissue. A realization of the pathologic changes which occur in prostatic hyperplasia will aid in elucidating this fact.

Benign prostatic hyperplasia consists in the growth of a single adenoma or multiple adenomas. By the process of growth these adenomas compress the surrounding normal prostatic tissue, thus forming the so-called surgical capsule of the prostate gland. Complete removal of the adenomas and exposure of the entire surgical capsule of the gland is the goal of any operation for benign prostatic enlargement, regardless of whether the approach is by suprapubic, perineal or transurethral means. Thus each operation is designed to achieve the same end, and the only possible source of controversy is the method of approach to the enlarged prostate gland; we do not propose to discuss this problem. It is sufficient to state that each surgeon must decide which operation in his hands is attended with the lowest mortality and morbidity rates and the best functional results.

Knowledge of what each operation fails to accomplish is of equal importance. In none of the operations is the entire prostate gland removed. In all the operations prostatic tissue persists in the form of the surgical capsule of the gland. The potentiality for the development of recurrent benign hyperplasia and prostatic carcinoma remains present to an equal degree regardless of whether suprapubic, perineal or transurethral prostatectomy has been performed.

REPORT OF CASES

The late development of carcinoma of the prostate gland after suprapubic prostatectomy was recently brought to our attention by the following case.

CASE 1—A man aged 56 first came to the clinic in 1916 complaining of symptoms of urinary obstruction of five years' duration. The obstruction finally had resulted in complete urinary retention. The patient appeared to be in good health, and results of physical examination were negative except for those of rectal palpation, which revealed benign prostatic enlargement graded 3 (on the basis of 1 to 4). Results of routine laboratory studies were within normal limits, a plain roentgenogram of the urinary tract disclosed no abnormality. The amount of the residual urine was 150 cc.

Suprapubic prostatectomy was performed and the tissue removed weighed 70 Gm (fig 1). Microscopic examination of the tissue revealed adenofibromatous hyperplasia. Convalescence was entirely uneventful, and the patient was dismissed from the hospital on the ninth postoperative day.

In 1924, eight years after the prostatectomy, the patient returned to the clinic because of asymptomatic pyuria; he had no symptoms referable to the urinary tract. Results of physical examination again were essentially negative, rectal palpation disclosed the prostate gland to be smooth and firm. Urinalysis revealed pyuria of grade 2, and a plain roentgenogram of the urinary tract disclosed no abnormality. Cystoscopy showed areal cystitis and pronounced relaxation of the internal vesical sphincter muscle. The prostatic bed appeared clear, and no adenomas were visible. Vesical lavage was advised and the patient was dismissed.

In 1933, seventeen years after the prostatectomy of 1916, the patient returned to the clinic complaining of initial hematuria of two years' duration, associated with urgency of micturition and dysuria. To rectal palpation the prostate gland was enlarged to grade 2, and a hard nodule was palpable in the region of the right seminal vesicle. Cystoscopy disclosed definite enlargement of the right lobe of the prostate gland and lesser enlargement of the left lobe. In the right lobe were two nodules which were suggestive of either small adenomas or carcinoma. Considerable granulation tissue was noted in the floor of the urethra, and a specimen of tissue, removed for biopsy from the prostatic region through the cystoscope,

Fig 1—Adenomatous tissue removed by suprapubic enucleation, case 1.

was reported as being inflammatory tissue. Local application to the prostatic urethra and vesical lavage were advised and the patient was dismissed.

The patient returned to the clinic for the last time nineteen years after prostatectomy, complaining of hematuria and symptoms of moderate obstruction. Cystoscopy disclosed a typical carcinomatous nodule under the mucosa of the urethra. Carcinoma was found in both lateral and median lobes.

prostate gland. Thirteen Gm of tissue was removed by trans-urethral resection, and microscopic examination disclosed adenocarcinoma of grade 3 (fig 2). The patient remained well for several years but hematuria became severe and constant and the patient died of carcinoma of the prostate gland in 1938, twenty-two years after prostatectomy.

Fig 2—Section of tissue removed from the prostate gland of the same patient from whom the adenomatous tissue shown in figure 1 had been enucleated nineteen years previously. This section shows unquestionable adenocarcinoma (hematoxylin and eosin $\times 100$).

There are several features of interest in this case. A large amount of benign, hyperplastic prostatic tissue had been removed by suprapubic prostatectomy and the patient was known to be well, save for slight asymptomatic pyuria, eight years later. Urologic examination at that time, including cystoscopy, did not reveal any evidence of prostatic carcinoma. Seventeen years after prostatectomy the patient returned for treatment, and at this time carcinoma of the prostate gland undoubtedly was present, in all probability the carcinoma had been present for the preceding two years. Rectal palpation disclosed a hard nodule in the prostate gland, in contrast to the results of previous rectal palpations. In addition cystoscopy revealed changes suggestive of carcinoma. Positive evidence of the presence of carcinoma was obtained at the time of the patient's last admission, nineteen years after prostatectomy.

The number of years which this patient lived, even though he was afflicted with a high grade carcinoma of the prostate gland, also is of interest. In spite of the fact that the patient received no specific measures for the cure of carcinoma of the prostate gland, such as radical prostatectomy, and received no treatment directed toward alleviation of the condition, such as orchietomy or the administration of estrogen, he lived comfortably for seven years before he finally succumbed to carcinoma of the prostate gland. This case clearly illustrates the fact that in the evaluation of any type

of therapy directed toward a given disease, it is imperative to consider the natural course of the disease.

The following case, illustrating the development of carcinoma of the prostate gland many years after perineal prostatectomy, also is of interest.

CASE 2—A dentist aged 65 first came to the clinic in 1909 complaining of symptoms of urinary obstruction of six years' duration. For three years previous to his admission he had been unable to void and had had to resort to catheterization. Six weeks before admission he experienced chills and fever and noted pain and swelling of the perineum and scrotum. By rectal palpation the prostate gland was found to be firm and to extend beyond the reach of the examiner's finger. A diagnosis of 'prostatic abscess' was made and perineal drainage was carried out. The patient responded satisfactorily. Three weeks later perineal prostatectomy was performed (fig 3). Microscopic examination of the tissue removed disclosed benign adenofibromatous hyperplasia. Convalescence was uneventful, but the patient experienced urinary incontinence for six months. Urinary continence was regained, however, and two years after perineal prostatectomy the patient wrote to us stating that he had no urinary symptoms and was enjoying perfect health.

The patient returned for the last time in 1919, ten years after prostatectomy. He stated that he had been perfectly well until the previous year, when he noted the onset of urinary frequency, dysuria and incontinence. Seven months before this last admission a mass had appeared in the right groin. By rectal palpation the prostate gland was found to be enlarged to grade 3 and unquestionably malignant. A lymph node removed from the groin for biopsy was reported by the pathol-

Fig 3—Tissue enucleated from the prostate gland by the perineal route in case 2.

ogists as being involved by metastatic adenocarcinoma. A permanent suprapubic cystostomy catheter was inserted but the patient failed gradually and died of carcinoma of the prostate gland in 1921, twelve years after the perineal prostatectomy.

The foregoing two reports illustrate the fact that prostatic carcinoma can appear many years after suprapubic or perineal prostatectomy. In an entirely analo-

gous manner, transurethral prostatic resection does not preclude the future development of carcinoma of the prostate gland. The following case clearly illustrates this point.

CASE 3—A man aged 64 first came to the clinic in 1934 complaining of symptoms of gradually progressive urinary obstruction of four years' duration. This condition finally had resulted in complete retention of urine. Physical examination revealed the bladder to be distended to the level of the umbilicus. By rectal palpation the prostate gland was noted to be enlarged to grade 2, resilient and smooth. The blood urea was 60 mg per hundred cubic centimeters of blood and a plain roentgenogram of the urinary tract disclosed nothing abnormal save hypertrophic changes of the lumbar portion of the spinal column. Transurethral prostatic resection was carried out in two stages and a total of 54 Gm of tissue was removed. Microscopic examination of this tissue revealed adenofibromatous hyperplasia of the prostate gland. Convalescence was uneventful, and the patient was able to void easily at the time of dismissal.

The patient returned in 1940, six years after transurethral resection, and stated that he had been perfectly well until the preceding two months, at which time he had noted symptoms of progressive urinary obstruction and finally complete retention. By rectal palpation the prostate gland was found to be enlarged to grade 3, but its tissue apparently was benign. The value for blood urea was 86 mg per hundred cubic centimeters of blood and a plain roentgenogram of the urinary tract disclosed hypertrophic changes of the lumbar portion of the spinal column. Transurethral prostatic resection was performed, and 45 Gm of tissue was removed. Microscopic examination of this tissue revealed adenocarcinoma of grade 4.

It is apparent, therefore, that prostatectomy performed either by suprapubic perineal or transurethral methods confers no immunity on the patient so treated against the subsequent development of prostatic carcinoma. Regardless of the type of operation performed, the potentiality for carcinoma remains present to an equal degree. A cursory examination of our records disclosed 5 other cases in which suprapubic prostatectomy had been performed at the Mayo Clinic and microscopic examination had revealed benign adenofibromatous hyperplasia. In each instance the patient returned at a later date, and a diagnosis of carcinoma of the prostate gland, verified by microscopic examination, was made. The interval between the time of prostatectomy and the time at which a diagnosis of carcinoma of the prostate gland was made varied from ten to eighteen years, the average was thirteen years. The carcinoma usually was of a high grade of malignancy, and the 3 patients who could be traced lived for an average period of eight months after the diagnosis of carcinoma had been made.

In addition, we have examined the records of 8 patients who had had suprapubic prostatectomy performed elsewhere many years previous to their admission to the clinic. To the best of our knowledge the prostatectomy had been performed for benign prostatic hyperplasia. The operation had been performed, on an average, sixteen years previous to the admission of the patients to the clinic. In each case tissue removed at the Mayo Clinic by transurethral prostatic resection disclosed carcinoma. With one exception the carcinoma was of a high grade of malignancy, that is, of grade 3 to 4. One patient died while he was in the hospital, the rest survived for an average period of thirteen months.

One of the advantages frequently ascribed to suprapubic and perineal prostatectomy is that they permit complete removal of a small carcinoma which has apparently remained localized within an adenoma. In

such cases, usually, the presence of a carcinoma is not considered before operation, and only microscopic examination discloses its presence. It is claimed that enucleation of an adenoma of this type will effect a cure. Although such a happy outcome remains exceedingly rare, we report the following case as a commentary on such a claim.

CASE 4—A man aged 57 came to the clinic in 1928 because of acute urinary retention of two days' duration which required decompression. Results of physical examination were negative excepting that rectal palpation disclosed benign enlargement of the prostate gland of grade 3. Cystoscopy revealed benign trilobar prostatic hyperplasia, and two stage suprapubic prostatectomy was performed, 30 Gm of tissue being removed. The pathologist reported that a small zone of carcinoma of grade 2 was located within the adenoma. No specific measures were directed toward treatment of the carcinoma, and the patient made an uneventful convalescence. He has returned to the clinic on numerous occasions since operation, and examination has failed to disclose any evidence of carcinoma. At the time of this report, fourteen years after prostatectomy, the patient is enjoying perfect health.

Despite what might be inferred, the cure achieved in the foregoing case does not attest any special advantage of the suprapubic method of prostatectomy. Prostatectomy performed by either the transurethral or the perineal route would have removed the same tissue and effected a similar cure. Just such a happy outcome is illustrated in the following case.

CASE 5—A man aged 66 came to the clinic in 1934 complaining of symptoms of progressive urinary obstruction of four years' duration. One episode of complete retention had occurred two weeks before his admission. Rectal palpation disclosed benign enlargement of the prostate gland of grade 2. Transurethral prostatic resection was performed, and 105 Gm of tissue was removed. According to the pathologist the tissue removed represented adenofibromatous hyperplasia of the prostate gland, one small zone of adenocarcinoma of grade 2 was discovered. Convalescence was uneventful, and the patient was able to void easily.

The patient returned in 1937 and stated that he had experienced no urinary symptoms until the preceding day, when he noticed gross hematuria that had rapidly disappeared. By rectal palpation the tissue of the prostate gland was considered to be benign, and cystoscopy disclosed numerous varicosities in the posterior urethra and several inflammatory cysts.

The patient returned the next year because of symptoms of mild urinary obstruction for which his home physician had advised operation. The prostate gland was considered to be benign on the basis of rectal palpation, cystoscopy likewise failed to reveal any evidence of prostatic malignancy. Enlargement of the lateral lobes was present, and 32 Gm of tissue was removed by transurethral resection. The tissue was examined carefully by the pathologist, but he was unable to find carcinoma.

The patient returned for the last time in 1941, seven years after the first resection. The purpose of his last admission was removal of his remaining teeth, as suggested by his home physician. He said he had not had any urinary symptoms, and the prostate gland was considered to be benign on the basis of rectal examination. To the date of the writing of this paper, eight years after resection, there has been no evidence of carcinoma of the prostate gland.

Although a small carcinoma may be localized within an adenoma, it is usually impossible, unfortunately, to cure the patient of carcinoma by enucleation or resection of the adenoma. Because of the early spread of carcinoma of the prostate gland through the perineural lymphatic vessels, regardless of the size or location of the primary lesion, the possibility of complete eradication of the neoplasm is not great. The following case illustrates this point clearly.

CASE 6—A man aged 65 first came to the clinic in 1932 complaining of repeated attacks of complete urinary retention requiring catheterization. Rectal examination disclosed a smooth benign enlargement of the prostate gland of moderate size. Cystoscopy revealed enlargement of both lateral lobes, without evidence of malignancy. Primary suprapubic prostatectomy was performed, and 36 Gm of tissue was removed. The pathologists' report was adenofibromatous hyperplasia with one microscopic area of beginning adenocarcinoma.¹

The patient returned two years later because of symptoms of urinary obstruction and pain in the sacrum. Physical examination revealed that the patient had lost weight and strength. The prostate gland, as palpated rectally, was enlarged, hard and fixed. A hard, fixed mass was palpable in the right inguinal region and was interpreted as being a metastatic malignant process. Transurethral prostatic resection was performed, and 8 Gm of tissue was removed; microscopic examination revealed adenocarcinoma of the prostate gland of grade 3.

COMMENT AND CONCLUSIONS

In conversations with physicians who are not urologists we have been impressed by their misconceptions concerning the three commonly performed operations for benign prostatic hyperplasia. Perhaps the most widespread misconception is that the performance of suprapubic or simple perineal prostatectomy precludes the subsequent development of carcinoma of the prostate gland or recurrent prostatic hyperplasia. This belief is entirely fallacious, and we have presented instances in which carcinoma of the prostate gland has occurred many years after such operations. This misconception can be corrected by the simple statement that normal prostatic tissue, in the form of the surgical capsule, remains regardless of whether suprapubic, perineal or transurethral prostatectomy has been carried out. Thus, the possibility of the development of recurrent hyperplasia or prostatic carcinoma is present to an equal degree irrespective of which one of these operations has been performed. The only operation devised to remove all prostatic tissue is radical perineal prostatectomy in which the entire prostate gland, a portion of the urethra, a cuff of the bladder, both seminal vesicles and about 5 cm of each vas deferens are removed. This operation, however, is employed exclusively in cases of prostatic carcinoma, and even by its most ardent advocates it is applied, with hope of cure, in only approximately 3 per cent of cases of prostatic cancer.

The surgical treatment of benign prostatic enlargement can be summarized by the statement that in each case it is necessary to remove a certain definite amount of hyperplastic tissue; this tissue can be removed through a suprapubic or perineal wound or through the urethra, and each surgeon must decide which method of approach is most suitable in his own hands.

One of the advantages frequently ascribed to suprapubic or simple perineal prostatectomy is the removal of an undetected carcinoma located within an adenoma. We have described such a case (case 4), but unfortunately the happy outcome in this case is extremely infrequent. Furthermore, although it is true that this apparent cure was achieved by suprapubic prostatectomy, it is undeniable that a similar cure would have been attained by the performance of either perineal or transurethral prostatectomy. More frequently than not, however, in spite of the fact that the carcinoma may be microscopic in size (case 6), the lesion has spread to the perineural lymphatic vessels, and in such a case cure by any of the three methods described herein is impossible.

THE USE OF CONCENTRATED RED CELLS AS A SUBSTITUTE FOR WHOLE BLOOD

IN THE TRANSFUSION THERAPY OF ANEMIA

ROBERT S. EVANS, M.D.

SAN FRANCISCO

It is well known that plasma is preferable to whole blood in combating the hemoconcentration of surgical shock. However, the use of the cellular portion of the blood in the transfusion therapy of anemia has not been widely discussed in this country. The present production of large amounts of plasma for war purposes leaves as a by-product the cellular portion of the blood. That it is practical to give this concentrated cellular portion without dilution in the form of multiple transfusions has been demonstrated by MacQuaide and Mollison¹ and Williams and Davie² in England. This method appears to have several advantages over the use of whole blood in the transfusion therapy of anemia. A larger amount of red cells can be given in the same total quantity, thus reducing the time and effort necessary to achieve the desired result. Patients with reduced cardiac reserve as well as anemia may be given transfusions of concentrated cells with less chance of producing failure of the left ventricle. If the concentrated red cells now available are used when indicated in place of whole blood, more plasma will be available for the treatment of shock.

My purpose in this report is to call attention to the use of concentrated cell transfusions as a substitute for whole blood in the treatment of anemia and to present some of the striking results obtained.

PROCEDURE

The material used was obtained from the Cutter Laboratories in Berkeley, Calif., where plasma is derived from blood collected by the Red Cross Blood Donor Service in a large West Coast area. The citrated whole blood is centrifuged at 2,400 revolutions a minute for twenty minutes and 250 cc of the supernatant plasma withdrawn by suction. The remaining 250 cc, consisting of red cells covered with a patchy layer of leukocytes and platelets, is transported to us in the original container the day after withdrawal from the donor. Each flask contains sufficient plasma to make the material liquid, and an even suspension of erythrocytes can be produced by gentle shaking.

Owing to the difficulty of transporting the material to Stanford Hospital at frequent intervals, only group O cells are used. The blood group is checked and the major cross match done before each transfusion. Samples for these and other determinations are withdrawn from the flask by sterile serologic pipets. The blood is stored at 4 to 6 C and is given without warming shortly after removal from the refrigerator.

The hematocrit value of 30 specimens varied from 84 to 95 per cent. Fifty per cent of these showed evidence of varying amounts of free hemoglobin in the

¹ From the Department of Medicine, Stanford University School of Medicine.

² The San Francisco Unit of the American Women's Voluntary Services dependably and efficiently transported the blood from Berkeley to San Francisco.

supernatant plasma. My associates and I confirmed the finding of others¹ that this does not necessarily indicate an increase in cell fragility as measured by susceptibility to hypotonic saline solution and probably represents spontaneous dehemoglobinization described by Kolmer.¹

The transfusions are administered with an ordinary recipient set consisting of a 300 cc cylinder connected to a Kaufman luer syringe by 4 feet of rubber tubing. The only filtering device is a double thickness of sterile gauze stretched over a funnel placed in the top of the cylinder. An 18 gage needle is used for all transfusions, and the rate of flow is controlled by gravity. If the reservoir is placed 3 feet above the antecubital space, 250 cc of the concentrated cells can be administered in forty minutes. A small amount of saline solution is used to start the intravenous infusion, but an appreciable dilution is not necessary to obtain a steady uninterrupted flow. In most procedures the cells from 2 or 3 pints of blood are given and the contents of the second or third flask added when the reservoir is nearly empty.

The patients receiving the transfusions were in both the clinic and the private services of the hospital. In all,

the cells from 92 pints of blood have been given to 30 patients in forty-four procedures. The clinical diagnoses of the group of patients are presented in table 1.

RESULTS

Hematocrit readings⁴ were made before the procedure was carried out and on the following day. Two hundred and fifty cc of concentrated cells produced an average rise of 2.9 per cent in the hematocrit value. The change in the hematocrit reading was proportional to the amount of blood given, so that 750 cc of concentrated red cells produced a rise of 8.5 to 9 per cent and a dramatic change in the appearance of the patient. Four cases are presented to illustrate the efficiency and efficacy of the method.

CASE 1—A white man aged 34 with a diagnosis of chronic nephritis, followed in the nephritis clinic for ten years, has been in a state of chronic uremia with associated anemia for five years. Mild cardiac failure developed with pulmonary edema in October 1942, but the patient made a good response to rest and digitalis. After returning to work he continued to have dyspnea on mild exertion and at times exhibited a gallop rhythm. It was thought that improvement in the oxygen carrying capacity of his blood might decrease cardiac work and

relieve his symptoms. As usual, his anemia (hematocrit reading 26) had shown no response to liver and iron therapy. He was admitted to the ward on Jan 13, 1943, where a 450 cc transfusion of concentrated red cells was given without difficulty or ill effect. The next day he received a second transfusion of an equal amount, following which his temperature rose to 38.3 C (101 F) rectally without the sensation of discomfort. There was no rise in blood pressure (190 systolic, 110 diastolic) following transfusion, and vital capacity (3,200 cc) was not diminished. The hematocrit reading was 40.5 when he was discharged the following morning. Four weeks later it was 35.5. In spite of the striking improvement in the anemia and general appearance, he did not experience great subjective change, although the dyspnea on exertion did diminish.

All 9 patients with uremia and anemia received 400 to 500 cc of concentrated cells at one time. None of these patients were in congestive failure but 4 had symptoms and signs which indicated that failure was imminent. One patient, a man aged 38 in the final stages of uremia, developed transitory pulmonary edema and orthopnea following a transfusion of 500 cc of concentrated cells. This was anticipated, since he had experienced bouts of paroxysmal dyspnea for several nights preceding entry. It is noteworthy that a patient in such a precarious condition could take enough blood to increase his hematocrit reading from 24 to 30 and hemoglobin from 44 to 63 per cent (Sahli) in a single procedure. Most of the 9 patients with anemia secondary to uremia experienced little improvement in general symptoms, but all were in fairly advanced stages with the blood creatinine level varying from 6 to 12 mg per hundred cubic centimeters. The cosmetic effect in diminishing the pallor was the most striking effect observed.

CASE 2—A woman aged 34 was brought to the hospital on Jan 22, 1942 during the eighth month of pregnancy because of extreme pallor. She had noted easy fatigue and dyspnea for only one week, although a history of blood loss or jaundice could not be obtained. She was very obese and there was considerable air hunger. The scleras were clear and the skin and mucous membrane pale. The size of the abdomen was consistent with an eight months pregnancy, and the fetal heart could be heard. The hemoglobin level was 20 per cent (Sahli) on entry. Her blood was Rh positive. Following one transfusion of whole blood the hemoglobin was 25 per cent (Sahli) and the erythrocytes numbered 1,490,000 per cubic millimeter. The hematocrit reading was 11.5 and by the Wintrobe standards all the cells were small (mean corpuscular volume 76.7 cubic microns) but well filled with hemoglobin (mean corpuscular hemoglobin 28.7 micromicrograms) (mean corpuscular hemoglobin concentration 37.5 per cent). The reticulocyte count varied from 2.3 to 3.3 per cent. The icteric index was 3 and the resistance of the erythrocytes to hypotonic saline solution was normal. Leukocyte counts were within normal range, platelets numbered 105,000 per cubic millimeter. Stool examinations were negative for occult blood.

The transfusion of whole blood given shortly after entry relieved the air hunger somewhat. The second hospital day she was given 450 cc of concentrated red cells, which raised the hematocrit reading to 20, and the hemoglobin to 40 per cent (Sahli). The patient continued to show a low reticulocyte percentage considering the degree of anemia, and five days later the hematocrit was still 20. She was given a second transfusion of 500 cc of concentrated cells, following which the hematocrit reading was 26.5. Stereal puncture showed erythroblastic hyperplasia. Following this she continued to improve on iron therapy. Two weeks later the hemoglobin was 75 per cent (Sahli), and the erythrocyte count 3,740,000 per cubic millimeter. She was discharged improved to return for delivery. The cause of her anemia remains in doubt.

4 Hematocrit determinations were done by the Wintrobe method.

This case illustrates several advantages of using concentrated cell transfusions. It was necessary to increase the oxygen carrying capacity of the patient's blood as quickly as possible, since premature labor could have begun at any time. There was considerable technical difficulty in finding superficial veins for intravenous infusion and it was a great advantage to reduce the number of procedures by half in order to achieve the same results as would have been obtained with whole blood transfusions.

CASE 3—A man aged 35 had been discharged from the hospital four weeks previously with a diagnosis of monoblastic leukemia and secondary anemia. During his hospital stay he had received a total of seven transfusions of whole blood, which raised the hemoglobin level from 26 per cent (Sahli) to 82 per cent at the time of discharge. He was readmitted on Jan 25, 1942 because of bleeding from the mouth following the incision of a peritonsillar abscess. He appeared acutely ill. The skin was pale and covered with petechiae. The tonsils were large, infected and covered with clots. The edge of the spleen was palpable. Examination of the blood showed a severe anemia and thrombopenia and many monoblasts in the circulating blood. He received one transfusion of 500 cc of bank blood and one of 600 cc of fresh citrated blood but continued to bleed from the mouth. Three days after admission the hematocrit reading was 18. He was given 750 cc of concentrated cells, which he took without discomfort or reaction. The following day he received an equal amount without incident. The capillary bleeding time fell from fifteen minutes to three and a half minutes and there was a cessation of oozing from the tonsillar incision. There was a questionable rise in platelets from 2000 to 10,000 on repeated counts, and the hematocrit level rose to 36. The tonsillar lesion responded well to local x-ray therapy. During the next two weeks in the hospital he received transfusions of 450 cc and 650 cc of concentrated cells. He was discharged at the end of the third week considerably improved with a hemoglobin level of 90 per cent (Sahli) and an erythrocyte count of 4,400,000 per cubic millimeter. Crops of petechiae continued to appear, however.

By use of the concentrated cell transfusions this patient received enough blood in twenty-four hours to double the volume of circulating red cells and bring his hemoglobin from a low level (35 per cent) to one approaching normal (70 per cent). Two of the patients with leukemia showed bleeding tendencies, which seemed to be as well controlled by transfusions of concentrated cells as by whole blood. There were no reactions to multiple transfusions in this particular group.

CASE 4—A white man aged 29, a welder, was admitted to the hospital on Feb 10, 1943 following the sudden onset of weakness eighteen hours before and passage of several tarry stools. He gave a history of epigastric distress after meals for the past several months. There was pallor of the skin and mucous membranes and the forehead was slightly moist but the extremities were not cold. The blood pressure was 120 systolic and 62 diastolic. The pulse rate was 138 a minute and he was moderately restless. There was an old fracture deformity of the left arm. Physical examination was not otherwise remarkable. The hematocrit reading was 18 and the hemoglobin was 40 per cent (Sahli). On entry he was given 500 cc of concentrated red cells. The following day the hematocrit reading was 23 and the hemoglobin was 50 per cent. He then received a second transfusion of 500 cc of concentrated cells. On the fifth hospital day the hematocrit reading was 31 and the hemoglobin was 62 per cent (Sahli). The plasma proteins were 5.7 Gm per hundred cubic centimeters. He improved rapidly on a soft diet and his hemoglobin level climbed steadily. Stools became negative to the guaiac test

for occult blood. A gastrointestinal series on the twelfth hospital day showed deformity of the duodenal cap, but an ulcer crater could not be demonstrated.

The treatment of anemia of acute blood loss with transfusions of concentrated cells presents a more complex problem than refractory anemias, since the loss of plasma proteins is not replaced. Investigation of the effect of acute blood loss in normal human subjects shows a steady fall of plasma proteins during an initial period of three hours following hemorrhage due to replacement of the plasma lost by protein poor fluid. Thereafter an increase in plasma volume is not accompanied by a further drop in protein. It is concluded as a result that the plasma volume is determined by the amount of circulating protein and that the normal mechanism for adding plasma to the circulation acts slowly over two or three days. Many patients suffering from severe gastrointestinal hemorrhage from a bleeding ulcer or ruptured varix are likely to have low plasma proteins at the time of onset.⁵ Protein replacement may be slower than in normal subjects because of poor reserves and restricted diet. In view of these findings it is evident that transfusions of concentrated cells should not be used as a substitute for whole blood in the treatment of acute blood loss without regard to the level of plasma proteins or plasma volume. Three of the 4 patients with anemia from blood loss in this series benefited a great deal from the transfusions, the fourth, an elderly man, died of other complications.

REACTIONS TO TRANSFUSION

A total of seven febrile reactions occurred following the forty-four procedures. Of these, four consisted of a rise in temperature of less than 2 degrees C (3.6 degrees F) and were accompanied by slight chilly sensations but no real discomfort. The others consisted of more prolonged febrile reactions beginning the day after a transfusion with the highest temperature recorded at 39.8 C (103.6 F) rectally. There were no subjective sensations except a feeling of warmth and headache, and the temperature was down to normal in twenty-four hours. One patient with a diagnosis of aleukemic leukemia had exhibited a similar reaction following a previous transfusion of whole blood. In only 1 instance did a severe chill occur followed by a high fever. This patient has experienced many similar reactions during the previous three years following transfusions with all types of blood for therapy of an aplastic anemia. All febrile reactions followed transfusions of 500 to 700 cc of concentrated cells. There is no evidence that free hemoglobin in the plasma was a factor in producing the febrile reactions. It appears from these figures that reactions to transfusion in this comparatively small group of cases did not represent a greater problem than with ordinary methods.

Fourteen of the 30 patients had blood of group O the remainder of A or B. Since small amounts of group O plasma were given hemolytic reactions from the introduction of incompatible isoagglutinins were not anticipated and none occurred. Seven hundred and

fifty cc of concentrated cells, the largest amount given at one time, consists at most of 15 per cent plasma, or less than half the amount given with an ordinary transfusion of whole blood. The color of the plasma compared before and after transfusion in the hematocrit tube showed a slight but detectable increase in bilirubinemia in 5 instances. The icteric index was never greater than 8 units, however, and the increase was not accompanied by a febrile reaction. The patient with chronic hemolytic anemia showed a decided increase in bilirubinemia, as was anticipated.

Hemolytic reactions due to the development of an anti Rh agglutinin after repeated transfusions have been reported.⁷ The severity of such an intra group reaction might be increased if a large amount of Rh positive cells were given to an Rh negative recipient who had been sensitized by previous transfusions. While not done in this series, special techniques of detecting anti Rh and other atypical agglutinins are doubtless advisable before large amounts of concentrated cells are given to patients in whom isosensitization may be a factor.

hypotonic saline solution have been made. Results of observations made by the method of Daland and Worthley⁹ are presented in table 2.

Decrease in resistance to hemolysis in hypotonic saline solution during the first week of storage of citrated whole blood has been observed by Kolmer and Howard³ and Crosbie and Scarborough,³ but the change was not as pronounced at the end of the first week as we observed it in cells stored without plasma. While our observations are not complete, they indicate that concentrated cell suspensions should be given within three days after withdrawal and separation from the plasma in order to obtain the most lasting results.

COMMENT

The use of the cellular portion of whole blood in the transfusion therapy of anemia is particularly important at the present time. A large amount of this material is being discarded because of lack of widespread recognition of its usefulness. It can be distributed easily and given at low cost to patients who might not otherwise receive transfusions. Concentrated red cells have a decided advantage over whole blood in the transfusion treatment of anemia, since fewer procedures are required to obtain the desired result and the hospital stay can be significantly shortened. There is no indication that the plasma content of whole blood is beneficial to these patients; it may be a decided disadvantage in the presence of reduced cardiac reserve. Our results so far indicate that concentrated cell transfusions are as efficacious as whole blood in controlling the bleeding tendencies of thrombocytopenia secondary to leukemia.

Of greater importance than these considerations is the use of concentrated cell transfusions in the place of whole blood as a means of saving plasma for war purposes. Whole blood given when only cells are needed represents the waste of so much plasma. No accurate figures are available for this institution, but it is estimated that at least one half of all transfusions given aim to correct anemia only. Physicians and hospitals using blood banks can save significant amounts of plasma by requesting only the cellular portion of the blood when that is all that is needed by the patient.

SUMMARY

Five per cent plasma with the cellular portion of blood for transfusions is sufficient to allow an even, uninterrupted flow with the ordinary recipient set and requires only a somewhat greater force of gravity. Single and multiple transfusions of type O cells have been given with good therapeutic results. The incidence of reactions does not appear to constitute a greater problem in the use of this type of blood. Blood from which most of the plasma has been removed is ideally suited for the transfusion therapy of patients with anemias refractory to other therapy and patients with anemia and reduced cardiac reserve. It is not so clearly indicated in the therapy of acute blood loss, since plasma proteins are not replaced.

Transfusions of concentrated cells might well be used when the cellular portion of the blood is all that is needed by the patient. If physicians and hospitals using blood banks will cooperate in requesting concentrated cells for transfusions, a large amount of plasma can be saved for war purposes.

EFFECTS OF STORAGE ON CONCENTRATED CELLS

All but two of the transfusions reported in this series were given within three days after the blood was withdrawn from the donor. Transfusions of 500 cc of concentrated red cells on the fourth and fifth day resulted in the anticipated rise in hematocrit value, although there is evidence that the rise was more transitory. One transfusion of 500 cc of concentrated cells, not included in this series, was given on the seventh day of storage. The resulting rise in hematocrit level persisted only forty-eight hours. The return of the hematocrit reading to the pretransfusion level was accompanied by an increase in the icteric index to 15 units. A second transfusion of cells stored for three days produced a rise in the hematocrit level that persisted without fall for seven days. Belk and Barnes⁸ have observed that the survival time of erythrocytes in citrated whole blood diminished with increasing rapidity after three days' storage. It is conceivable that erythrocytes of citrated blood will undergo even more rapid deterioration if the bulk of the plasma has been removed.

Preliminary observations as to the effect of storage on the susceptibility of erythrocytes to hemolysis with

RESULTS OF SURGICAL TREATMENT
OF VARICOSE VEINSGERALD H. PRAATT, M.D.
NEW YORK

The exceedingly high incidence of vascular diseases among those living to the age of 40 has made the study of therapeutic methods to care for these vascular lesions of interest to all. A thorough survey recently completed of 537 employees of a large department store who had worked for fifteen years or more, and all of whom were over 40, showed the surprising x-ray evidence of arteriosclerosis of 46 per cent. In this group only 12 per cent had subnormal oscillometric readings, therefore the arteriosclerosis was subclinical and unless x-ray films had been taken the person would not have been aware of the condition. Men and women differed both in incidence and in degree of arterial changes. While there was x-ray calcification in 44 per cent of the men, only 18 per cent of the women showed roentgenographic changes. In the group with advanced changes (plaques and the like) there were 30 per cent of the men but no women. It may be that further study will show that, like the graying of hair and wrinkles, arterial changes are metabolic and not pathologic unless some accident causes occlusion.

In the same study it was found that 40 per cent of the men and 70 per cent of the women had varicose veins which were pathologic and were causing symptoms. The sex difference was most interesting. The higher rate among the women could not be based on the pregnancy factor alone, as when those who had had pregnancies were eliminated the incidence was still 60 per cent, or nearly twice as great as among the men. It would appear, then, that the male deteriorates on the arterial side and the female on the venous. Efforts to determine the cause for the sex difference in the incidence of varicose veins have not been conclusive, but it does appear that a structural difference in the pelvis and perhaps the congestion of the menstrual cycle play a part, with pregnancy and its complications being the precipitating cause.¹ Despite the causes, it is apparent that 2 out of 3 women who continue actively at work eventually will develop varicose veins and be candidates for the complications of varicose veins, namely phlebitis or ulceration. In a total war men are subjected to strains that most of them are ill prepared to withstand. The long periods of standing, fights through jungles and against icy winds and adaptation to the peculiar positions necessary to man tanks, cramped cockpits or fox holes will all be registered as precipitating factors in the development of future vascular lesions.

Civilians will be more affected than usual. Older persons will take their places at tedious standing positions, operating unusual pedal apparatus and in general utilizing parts of the body not acclimated for the strain. One can expect a great increase in these lesions with this new precipitating factor, and, from the requests for information from the various camps, the armed services are already experiencing these problems. The treatment of a condition which affects such a large group is therefore a timely subject.

When the valves in the superficial veins have become incompetent, surgical treatment is the only type that can

be helpful. In our clinic 4 out of 5 patients have these valve incompetences and therefore resection of the saphenous vein is required. In private practice, in which neglect is not so uncommon, two thirds of the cases still come to operation.

In the selection of the patient for operation certain tests are important. These are:

1. Determination of arterial supply. The history will be important, as claudication, temperature and color changes in the skin, a history of frequent infections or diabetes mellitus are significant. Palpation of the major arteries, determination of the oscillometric readings and at times x-ray examination will be helpful in determining which of the patients have an arterial disease. The simple question "How far can you walk?" will be effective if arch and other ambulatory difficulties are eliminated.

2. Determination of deep vein patency. A history of phlebitis or "milk leg" is important. A test can be done readily by taking careful circumferential measurements at set points in the thigh, calf and ankle, then applying Ace type bandages and tourniquets with the veins empty, permitting the patient to walk for ten minutes and then remeasuring. In the normal person there will be a decrease in the circumference. Increase in size or pain is an indication of deep vein closure. An improved modification in the measurements in this test can be made by noting the displacement in a tank of water before and after walking.

3. The adequacy of the saphenous-femoral valve. This is readily demonstrated by elevating the patient's leg and emptying the veins, applying the tourniquet high in the groin and, with the patient standing, removing the tourniquet and noting whether the veins fill from above or below. A rapid filling from above indicates valve failure.

4. Testing for the incompetent communicating branches. An Ace bandage is applied from the toes to the groin and a tourniquet placed on the thigh above this area. As the bandage is removed, a sudden protrusion of a collection of veins shows the point of incompetence. A second Ace bandage, which may be wrapped from above down, exposes only a small area at a time and is helpful. All those "blow outs" or valve incompetences then are scheduled for operative resection.

Our study reveals that 80 per cent of those registered at the clinic have incompetent valves and require operative treatment. It must be remembered that this clinic is located in downtown New York in a section where people of a low economic status live and where self neglect is not unusual.

OPERATIVE TECHNIC

Experience has illustrated the importance of certain technical points in the operation. Only local anesthesia should be used, and simple infiltration from a single needle puncture (thus reducing danger to infection) is entirely satisfactory. Approximately 80 to 100 cc. of 1 per cent procaine hydrochloride is the average amount. The location of the saphenous vein at the femoral junction can be determined by the "one by one rule." 1 inch lateral and 1 inch below the spine of the pubis. The spine of the pubis is palpable even in obese persons. A transverse incision is chosen because it is in the line of skin cleavage and therefore heals more readily. Blunt dissection will expose the vein which on the average is

11 mm in diameter. Elevation of the saphenous vein with a tape assists in the demonstration and resection of each of the branches entering the bulb. The inferior epigastric and circumflex iliac branches may be so high on the bulb that retraction above the inguinal ligament

Fig 1—Anatomy of the area of the saphenous femoral valve junction of saphenous vein and the femoral vein 1 inch lateral and 1 inch below the spine of the pubis, the superficial pudendal artery shown crossing the bulb is a good guide to the junction point. The branches of the saphenous vein illustrated are the superficial circumflex iliac, the superficial inferior epigastric, the superficial pudendal, the superficial medial and the lateral femoral cutaneous. Note that high retraction is necessary to expose all branches.

frequently is necessary to expose them. The anatomic junction of the saphenous vein with the femoral is difficult to demonstrate because of the dilated bulb present when the saphenous femoral valve is incompetent. The superficial pudendal artery (fig 1) crossing the bulb is a good guide to this point. After resection of these and the other branches (external pudendal, medial and

Fig 2—Dissection in the saphenous fossa, branches resected, femoral end ligated, distal end of saphenous opened, catheter inserted, solution introduced retrogradely as the catheter is withdrawn.

lateral femoral cutaneous veins), the saphenous vein should be divided 3 to 4 inches below the bulb, dissected up to the femoral junction and ligated flush with the femoral vein by a transfixion suture. The distal end is then opened and the saphenous vein sclerosed by the retrograde insertion of a solution through a ureteral

type catheter.³ This method permits even distribution of the solution throughout the course of the vein, and larger amounts can be introduced than are usually employed (fig 2).

Animal experiments demonstrate that even at a distance of 2½ inches from the injection point intimal sclerosis is minimal. This testifies for the good results obtained by spacing the maximum sclerotic effect along the entire vein tree by the catheter method. If there are no contraindications (arterial disease, open ulcer), approximately 20 to 40 cc of 3.5 per cent sodium ricinoleate may be introduced. The size of the vein is a good guide to the amount of solution to be utilized, as in the larger veins the increased blood content reduces the strength of the sclerosing solution. In small veins a relatively smaller amount of sclerosing

Fig 3—Resection of communicating branch ('blowout'). Note perforating branch which must be resected together with the saphenous.

solution is indicated. The distal end of the saphenous vein is then resected, transfixed and ligated. While the saphenous vein and its branches are being exposed in the groin, an assistant dissects the secondary point together with a section of the saphenous and the communicating branch (fig 3). These are resected at the time the solution is introduced. The wounds are closed without drainage and are sealed, pressure pads are placed along the course of the saphenous vein and an Ace type bandage is applied from the toes to the groin. Our experience has demonstrated the value of steel wire suture material, and it is used exclusively.⁴ The patient walks around the room at once and thereafter for fifteen to twenty minutes out of every hour. At the end of an

⁴ Pratt G. H. Nine Years Clinical Experience with Steel Wire Suture Material, *Surg. Gynec. & Obst.* 74: 845 (April) 1942.

hour the supporting bandages are removed and the legs are inspected for collections of excess sclerosing solution, as shown by discolorations. Extra pressure pads are applied at these points and the bandage is reapplied. The latter part of the technic is important in preventing sloughs and since its adoption has reduced sloughs to 0.5 per cent.

RESULTS

My associates and I have reexamined and obtained follow-up results on 357 patients who have been operated on during the last six years with the technic described. There were 224 women and 133 men. The average age was 45 for the men and 41 for the women. Of these patients 9.6 per cent had the operation on the two legs at the same time and the operations on the remainder of the group were equally divided between the right and the left leg. Of the women 26.1 per cent and of the men 20.7 per cent had open ulcers at the time of operation. Of the women who gave an etiologic history (46.8 per cent of the total) 59.2 per cent considered pregnancy as the cause. The other causes are given in table 1.

The indications for the operation were

- 1 Incompetent saphenous femoral valves
- 2 Incompetent communicating branch valves
- 3 Varicose veins after phlebitis, when the phlebitis was inactive and the thrombosed vein had recanalized leaving the collateral dilated veins as pathologic varices

All of these patients were carefully examined and an estimate of the success of the procedure was made. The results necessarily are influenced by the personal factor of the examiner, but in these cases this influence was minimized by examination by several men at the same time. To have some criterion as to the results, the following standards were required:

- A Excellent, or 4 plus, results were those in which the patient was symptom free with no veins apparent and was given less than four subsequent injections.
- B Good results, or 3 plus, were those in which the patient was symptom free, without recurrence, and was given less than eleven subsequent injections.
- C Poor results, or 2 plus, were those in which there

Thirty-one per cent of the men and 28 per cent of the women had some concurrent disease such as hypertension, diabetes, arteriosclerosis and cardiac lesion.

were some symptoms, some veins were apparent even after subsequent injections or obvious technical errors, such as failure to resect secondary blowouts, were apparent. D The failures, 1 plus, were those in which the patient had symptoms—varicose veins were present or ulcers had reopened (table 2).

The average number of secondary ligations necessary was 2.3. The average percentage of the men who needed secondary injections was 23.4 and of the women 25.5.

The number of results reported as good or excellent is relatively high and is due partly to the fact that in some of the cases there has not been sufficient time for recurrences to develop. It is my hope that eventually 75 per cent of those operated on will fall in the good or excellent result class. Of the other 25 per cent, approximately one eighth will be failures due to technical error in resecting branches in the groin and one fourth to failure to resect the communicating branches accurately,

TABLE 2—Results of Vein Resection

	Male	Female
4 plus Symptom free no recurrence less than 3 injections	53.6%	50.6%
3 plus Symptom free less than 10 injections	30.9%	30.6%
1 plus and 3 plus	89.5%	93.2%
2 plus Only fair some local recurrences	6%	4.9%
1 plus Poor results recurrence or ulcers re-opened	4.5%	1.9%

and the rest to the development of a new incompetent communicating branch.

It is important to emphasize that varicose veins as a result of phlebitis are a different type of vein, the treatment must be varied and the results cannot be as satisfactory as in the simple varicosities. While it is not in my province to discuss phlebitis at this time, it is well to emphasize that in my opinion varicosities after phlebitis should not be operated on until there is evidence of subsidence of the inflammation and complete recanalization of the phlebotic veins. Contraindications to the procedure are:

- 1 Active and continuing phlebitis. All other clinics have not made this a contraindication. I have seen two fatalities after ligation in the presence of phlebitis. I feel certain that ligation does not prevent pulmonary embolism, as I have observed pulmonary embolisms many times after ligation.
- 2 The closure of the deep veins. Under no condition should superficial or collateral veins be resected or sclerosed if the deep veins are not open.
- 3 The presence of an acute infection in the leg, such as cellulitis.

Arterial disease is no longer considered a contraindication to operation on varicose veins, as I have seen sufficient clinical improvement and reduction in claudication time to advocate the procedure therapeutically. When one considers that the arterial and venous systems in the capillaries are continuous, it is apparent that any increase in the back pressure, i.e. varicose veins, will be transmitted back to the arterial side of the capillary bed with greater peripheral resistance to the arterial flow. Reduction of this peripheral resistance by elimination of the stagnant veins thus will aid the arterial flow. The same discussion applies to patients with heart disease and congestive failure. Certain patients with heart disease definitely improve after removal of this large pool of blood in the venous system—at times as dramatically as after phlebotomy.

SUMMARY

- 1 With an increase in life expectancy many patients with vascular diseases will require therapy. This is true of both arterial and venous lesions, but to a greater extent of the latter.

- 2 Total war with the severe demands on both military and civilian populations will be an active precipitating cause for an increase in venous problems.

3 If the major valves connecting the superficial and deep vein systems are incompetent, surgical therapy is necessary (60 to 80 per cent)

4 The technic effective in treating these patients is simple and safe if certain criteria rule in the selection of patients

5 The results after a six year follow-up of patients so treated are good in a high percentage

RADIATION THERAPY OF ACUTE SUBDELTOID BURSITIS

ARTHUR A. BREWER, M.D.

ALTON, ILL.

A. D.

OSCAR C. ZINK, M.D.

ST. LOUIS

Since Codman's¹ original description of subdeltoid bursitis in 1906, many articles on this subject have appeared in the literature. All aspects of the condition and numerous methods of treatment have been repeatedly presented.

A number of investigators have shown that irradiation is the treatment of choice in certain types of cases. However, these reports have appeared chiefly in the radiologic literature, with comparatively few in general publications. Therefore we wish to verify and draw attention to the merits of roentgen treatment of the painful shoulder.

A great many articles are available³ presenting detailed reviews of the etiology, pathology, symptomatology and the like, so that only brief mention of these need be made here. The condition has been designated by a variety of names: subdeltoid bursitis, calcarea peritendinitis, periarthrititis of the shoulder, calcifications of the supraspinatus tendon or simply painful shoulder. By common usage it is most often called subdeltoid bursitis.

There is no definite cause, although overuse and unaccustomed use of the arm are frequently factors. This was well shown by Bosworth,⁴ who found a definitely higher incidence among typists than among clerks employed by the same company.

Sandstrom⁵ and others have shown that the calcium usually present lies in the tendinous and peritendinous tissues and demonstrated that this calcium is deposited in preexisting degenerative tissue. Microscopically the bursa itself is not involved except for the posterior wall, which lies in contact with the supraspinatus tendon. Grossly the bursa is usually found to be bluish and tensely distended with a thick whitish material which is described as looking like tooth paste.

A division into acute and chronic groups is essential in attempting to evaluate any type of treatment. A sub-

acute division is also often mentioned, however, the subacute and chronic cases tend to merge and are here considered as a single group.

Acute subdeltoid bursitis presents a very typical clinical picture. There is a rather sudden onset of severe pain in the shoulder, usually with no history of significant trauma. Exquisite point tenderness may be elicited over the area of the subdeltoid bursa, with pain radiating down the arm, limitation of motion, and muscle spasm. The patient is apprehensive about any attempts to move the arm, and there is no doubt that he has severe pain.

Roentgenograms should be made to rule out bone and joint disease. In typical cases the diagnosis of bursitis frequently will be verified by the demonstration of a deposit of calcium just lateral to the greater tubercle of the humerus. So that this deposit is not obscured by overlying bone, it may be necessary to make roentgenograms with the humerus in both internal and external rotation, fluoroscopy is often of value in determining the optimum position for demonstrating the calcium.

Chronic cases present similar but much less pronounced symptoms. The duration is several weeks, months or longer. The onset is usually insidious, although an occasional acute case may become chronic because of inadequate treatment. There is usually decided limitation of motion or an actual "freezing" of the shoulder.

Numerous methods of treatment have been enthusiastically advocated, each usually reflecting the principal interest of the proponent. The most frequently cited methods appear to be irrigation,⁶ incision,⁷ exposure,⁸ physical therapy⁹ and manipulation. Any of these methods may produce relief of symptoms and a cure. Rest alone will be beneficial, often resulting in complete absorption of the calcareous deposits.¹⁰ Therefore statistics based on cure or improvement do not offer an adequate basis for evaluating the efficacy of the various types of therapy. The treatment of choice should be that one offering the shortest period of disability.

With these criteria in mind we have reviewed a series of cases treated with radiation. The first report of such a series was presented by Lattman¹¹ in 1936, and in his series 15 of 20 patients treated were relieved of pain within forty-eight hours. This was closely followed by the work of de Lormier,¹² who achieved similar results. Since then Pendergrass and Hodes,¹³ Chapman,¹⁴ Klem and Klemes,¹⁵ Baird,¹⁶ Sandstrom⁵ and others have verified these claims.

The physical factors employed are 200 kilovolts (constant potential), 18 milliamperes, 0.5 mm of copper plus 1.0 mm of aluminum filter (1.18 mm of copper half value layer), 50 cm target skin distance and a 10 by 15 cm port directed toward the anterolateral aspect of

the involved shoulder. A single treatment with a dose of 300 roentgens is usually sufficient although this may be repeated in from seven to ten days if there has been definite but incomplete relief.

The typical response in an acute case is a frequent but not inevitable aggravation of symptoms for eight to twenty-four hours. It is well, therefore, to provide adequate analgesics and place the arm in a sling during this period. This short period of aggravation is followed by rapid relief of pain and limitation of motion, so that in most instances the patient is able to resume his normal activities in from twenty-four to forty-eight hours after treatment. Residual tenderness usually disappears in a few days, and the calcium deposits will be absent in many instances if roentgenograms are repeated in a few weeks. The results are often quite startling both to the patient and to the referring physician.

Such were the results obtained in 11 out of 14 cases. Each of the 11 patients was able to resume normal activity within forty-eight hours. It is this rapid resumption of normal function that demonstrates the striking effect of roentgen treatment, and it is our belief that with no other form of therapy can so many patients be returned to normal activity so quickly.

If there has been no improvement at the end of forty-eight hours, operative treatment should be considered, and excision of the bursa was done in 2 such cases in this series. The third, a compensation case, was referred to a psychiatrist by the orthopedist and was lost for follow-up.

It should be noted that essentially similar results have been achieved in many more cases. However, these could not be included in this report because definite details of time of disability could not be ascertained in some and the original disability was not of sufficient significance in others.

A typical case is that of a typist who has had each shoulder involved at separate times. The first, in 1932, was on the left side, and at that time she was treated with diathermy and heat applications. She was completely disabled for a full month, three weeks of which time she was a hospital patient. Two years ago an acute subdeltoid bursitis suddenly developed on the right side and she was promptly given irradiation. The usual twenty-four hour aggravation was followed by rapid relief, and she resumed her work during the second twenty-four hours. In both instances calcium deposits were demonstrable, and there was a permanent cure with absorption of calcium. The variation in length of disability, however, was remarkable.

The impressive feature of roentgen treatment, then, and one of utmost importance to the patient, is the short period of disability as compared with any other method of treatment. In every successful case it was possible to resume normal activity within forty-eight hours. Time saved for doctors and hospital personnel is also of some importance.

For these reasons we believe that the treatment of choice for acute subdeltoid bursitis is irradiation. If within forty-eight hours there is no improvement, such treatment may be considered a failure and more radical procedures contemplated. Thus the patient is given the advantage of what is often the simplest and quickest relief obtainable, while if he is one of the small minority who will not be benefited he has lost comparatively little.

Unfortunately a similar response cannot be claimed for chronic bursitis. Approximately 30 per cent of the patients are improved in varying degrees, but only an

occasional patient is cured by this method. If definite symptomatic relief is not apparent within ten days after treatment, we feel that the treatment must be considered a failure. If partial but incomplete relief is reported, then further treatments are justified.

It should be noted, however, that these shoulders respond poorly to any type of therapy, and it seems reasonable to submit such a patient to a trial of radiation therapy before instituting more radical measures. Several such cases in our series have shown improvement to such an extent that the operation or manipulation planned was not necessary.

CONCLUSIONS

1 The length of the patient's disability should be the chief criterion for evaluating therapy of acute subdeltoid bursitis.

2 Roentgen therapy of acute bursitis results in a high percentage of cases in which the economic disability of the patient is reduced to less than forty-eight hours. Therefore roentgen therapy is the treatment of choice in this condition.

3 A trial of roentgen therapy is justified for the chronic type of subdeltoid bursitis.

ENDOMETRIAL TUBERCULOSIS AS A CAUSE OF STERILITY

E. RABAU, MD

I. HALBRECHT, MD

AND

J. CASPER, MD

PETAH-TIQUA, PALESTINE

Genital tuberculosis in the female is a disease mainly of the procreative period. Kelly¹ was unable to find more than 21 cases of genital tuberculosis in patients under 15 years. Hegar,² however, found it more frequently during childhood, although he admits that it appears mainly between the ages of 16 and 25. These authors also emphasize the fact that genital tuberculosis during childhood often remains unrecognized because of its atypical symptoms.

The frequency of genital tuberculosis decreases from the tubes toward the pelvic outlet. The tubes are affected most frequently (85 to 90 per cent). The reports concerning the general incidence of female genital tuberculosis and the incidence of tuberculosis of the different organs (namely the ovaries, myometrium, endometrium, and cervix) vary considerably.

In evaluating the results of the various statistical examinations one has to distinguish between women whose genitals are the only obviously affected system and a second group who show additional specific changes somewhere else.

In the latter group the diagnosis of genital tuberculosis is more likely to be made because one is more prone to think of a specific process of the genital organs in this group.

It must be remembered that the diagnosis of genital tuberculosis is difficult except when a tumor is present. Such instances, as is well known, are rather rare. The majority of women with genital tuberculosis show very few clinical symptoms and the condition is usually not

Professors Klopstock and Dr. Bregman made the bacteriologic examinations.

discovered at all or is discovered only by chance during operation or postmortem examination

Several methods have been proposed for facilitating the detection of genital tuberculosis. Daniel and Sormani³ inject a solution of dyes into the Douglas pouch and test its excretion into the urine. In the case of

Fig. 1—Giant cell tubercles in the stroma of the uterine mucosa and on the margin of glands

adnexal tuberculosis this excretion is said to be diminished

Wilson¹ maintains that in adnexal tuberculosis the Aschheim-Zondek test is positive. By others salpingography (Portes and his co-workers⁴) and pneumoperitoneum (Winz-Dyloff⁵) have been recommended. We have had no personal experience with these methods.

Heynemann⁶ is correct in saying that the diagnosis of genital tuberculosis of women has not profited by the recent progress in the field of tuberculosis and is, as formerly, almost always left to chance.

A hypoplastic uterus is an important clinical sign suggesting genital tuberculosis. Heynemann states that it is a predisposing factor for the localization of tuberculosis in the uterus. Sellheim⁷ suggests that the atrophy is secondary to tuberculosis; at any rate it is important

Fig. 2—Penetration of tuberculous granulations into glands

that in the presence of a hypoplastic uterus the possibility of genital tuberculosis should be suspected.

Since sterility frequently coincides with a hypoplastic uterus, one should suppose that genital tuberculosis might be found more often in these cases. Obvious as

this idea seems to be, it is striking how little attention is paid to it in the literature.

What is stressed is the well known fact that a latent tuberculosis of the salpinx is quite frequently discovered only during an operation for sterility. It is further known that the inflammatory adnexal tumors which occur after salpingography probably are, in the majority of cases, specific hydrosalpinx or pyosalpinx originating from a latent tuberculous adnexitis. It is therefore not only useless but even dangerous to attempt to diagnose latent tuberculosis of the salpinx by salpingography. We ourselves know of 5 cases of inflammatory adnexal tumors which flared up after salpingography and later on turned out to be of tuberculous origin.

We report here results which confirm to an unexpected extent the coincidence between sterility and genital tuberculosis.

During the last two years we have done endometrial biopsies by means of strip curettage in cases of sterility in order to investigate the development of the cycle in the uterus mucosa and to prove or disprove the existence of normal ovulation. As a result we have found a considerable number of cases of tuberculosis which had not given rise to any other sign or symptom.

Fig. 3—Greater magnification of figure 1, showing giant cell tubercles on the margin of a gland

METHOD

On the whole, 208 endometrial biopsies have been carried out by us in cases of sterility. As a rule the curettage was done one to two days prior to the expected menstruation. The material obtained was fixed in 10 per cent solution of formaldehyde embedded in paraffin and stained with hematoxylin and eosin. On a number of patients showing microscopic tuberculous changes a second curettage was carried out and the material obtained was inoculated into guinea pigs as well as transferred on a suitable medium for culture.

Furthermore, it was possible to examine clinically and roentgenologically almost all of the women showing endometrial tuberculosis for other evidence of tuberculosis. In many cases the urine of the women was sent for culture. In a number of cases it was possible to examine bacteriologically the urine and sperm of the husbands.

RESULTS

There were 20 cases in which tuberculous endometritis was found microscopically.

The main tuberculous changes were epithelioid and tubercles with giant cells in varying numbers and dis-

³ Cited by Caffier, P. *Zentralbl. f. Gynak.* 59: 2833 (Nov. 30) 1935.

⁴ Halban, Joseph, and Seitz, Ludwig. *Biologie und Pathologie des Weibes*, Berlin Vienna, Urban & Schwarzenberg, 1926, vol. 5, p. 341, part 1.

times conglomerate tubercles. We did not find caseous changes. Frequently tuberculous granulations had penetrated into the lumens of the glands. Secondary nonspecific inflammatory changes were a rule in quite a number of cases (figs 1, 2 and 3).

It is noteworthy that the uppermost layers of the mucous membrane were sometimes studded with numerous tubercles (fig 4).

It is remarkable that in spite of the tuberculous changes present the different stages of secretion and proliferation were fully developed in a high percentage of the cases (fig 5).

In some cases premenstrual hyperplasia was developed. In a few instances tubercles were found in an inactive atrophic endometrium (fig 6).

On 4 women we performed a second curettage and examined the material by means of animal experiment and culture. All four cultures and three experiments on animals proved positive for tuberculosis. The fourth animal died prematurely.

In 18 of the 20 positive cases an examination of the lungs could be made, including x-ray examination. There was no evidence of active tuberculosis of the lungs in any of the cases.

Fig 4—Numerous tubercles in the upper layers of the uterine mucosa.

The sedimentation rate of erythrocytes was normal in 10 women examined. In only 3 cases was pleurisy mentioned in the history.

The age of the women was from 19 to 42.

Gynecologic examination did not reveal in any of the cases even the most trifling evidence of genital tuberculosis. Only 1 woman was primarily amenorrheic, a second one had not menstruated for six months and a third one menstruated every three or four months. Four were hypomenorrheic and 2 suffered from menorrhagia. In the remaining 12 cases no irregularities of the cycle or of menstruation could be ascertained. Sterility was the only complaint which caused these women to seek medical advice.

COMMENT

Tuberculous endometritis is only seldom thought of. As a rule it is found only by chance either at the occasion of a curettage made for other reasons or after microscopic examination of a uterus removed at operation or autopsy.

Dominguez⁶ found among his clinical material of 5,516 cases only 5 cases of tuberculous endometritis.

Dominguez C M Ann Brasil de gynec. S 93 (Aug) 1939

Diethelm and Ramsey⁷ ascertained among the 3,647 microscopic examinations on the female genital tract 30 cases of genital tuberculosis. In only 1 case was the tuberculosis restricted to the endometrium.

Even among women with active tuberculosis of the lungs tuberculous endometritis does not seem to be of

Fig 5—Giant cell tubercles in the stroma of a fully developed premenstrual hyperplasia.

frequent occurrence. Lackner and his co-workers⁷ found among a group of 125 women with active tuberculosis of the lungs treated in the tuberculosis section of the Cook County Hospital only 2 cases of endometritis by means of curettage.

The high number of cases of tuberculous endometritis found by us in sterile, otherwise healthy, women points to a more than accidental connection between latent tuberculosis of the female genital tract and sterility.

On the basis of our results we have every reason to believe that many women with no obvious cause for their sterility suffer from latent genital tuberculosis. We have found tuberculous endometritis in about 10 per cent of our cases. But it is quite possible that in more than 10 per cent a latent genital tuberculosis was present and could have been proved if we had at our

Fig 6—Tubercle in an atrophic uterine mucosa.

disposal other diagnostic methods than strip curettage. Certainly through a complete evacuation of the mucosa more cases of tuberculosis would be made evident than by the use of the strip curettage only. As proof of this,

6 Diethelm M W and Ramsey T L. Am J Obst. & Gynec. 30: 420-424 (Sept.) 1935.

7 Lackner J E, Schiller Walter and Telford A S. Am J Obst. & Gynec. 40: 429 (Sept.) 1940.

we mention a case which showed normal mucosa in the first curettage but undoubted tuberculosis in the second curettage

Furthermore, attention must be drawn to the opinion prevalent among pathologists and clinicians that the tubes are much more frequently affected than is the endometrium and that all women suffering from tuberculous endometritis suffer from endosalpingitis, whereas the latter need not always be associated with an endometritis. If this opinion is correct a still higher incidence of genital tuberculosis must be assumed in our series.

Lackner found in a series of 113 autopsies on women suffering from tuberculosis of the lungs 58 per cent tuberculous adnexitis and only 17 per cent endometritis. If this percentage is applied to our patients, we should have to assume a percentage of 30 per cent of tuberculous adnexitis.

We are justified, therefore, in stating that genital tuberculosis plays a much greater part as a cause of sterility than has been supposed up to now.

It still remains undecided whether the endometritis or the salpingitis accompanying it is the cause of the sterility. At any rate, it is not always a question of the patency of the tubes. Tuberculous endometritis is quite compatible with patent tubes, for insufflation tests in 5 of the 20 cases which were now positive had formerly been positive.

The path of infection of the uterine mucosa is uncertain. Hematogenic or lymphatic origin and intracanalicular extension from the tubes have to be considered. In favor of the latter is the fact that tuberculous salpingitis is more frequent than endometritis. Against the hematogenic origin stands the fact that tuberculosis of the ovaries is comparatively rare. If the hematogenic origin of infection were the usual one, the ovary, the tubes and the endometrium would probably be equally affected. It is improbable that there exists a primary tuberculous endometritis. As far as is known, endometritis is nearly always a secondary lesion.

The possibility of exogenic infection through a tuberculous partner by sperm containing tubercle bacilli seems to be negligible. The few specimens of sperm examined by us for tuberculosis by means of culture gave negative results. Other authors came to the same conclusion.

The problem of therapy seems difficult at present. A radical operation, as proposed by several authors, appears as a rule unjustified. The fibrotic form of tuberculous endometritis is to be interpreted as a sign of self healing. Radical surgery, therefore, should be reserved only for caseous processes. The experience with x-ray and radium irradiation is too small to allow a final conclusion.

SUMMARY

In a series of 208 sterile women examined by strip curettage 20 cases of tuberculous endometritis were found.

In those cases in which curettage could be repeated, the diagnosis was confirmed by inoculations into animals or by culture.

In none of these cases had tuberculosis previously been suspected.

Subsequent clinical and roentgenologic examinations failed to disclose any sign of active tuberculosis elsewhere.

ADDENDUM—Since the paper was written 9 more cases of tuberculous endometritis have been found by us.

Clinical Notes, Suggestions and
New Instruments

MYOCARDIAL ABSCESS

NATHAN FLAXMAN, M.D., CHICAGO

Abscess of the myocardium in itself is not important, but it can serve to emphasize the significance of the underlying infection. The literature on the subject is scant. Most of the reports in the older literature consist of a gross description of the heart without any information on the clinical course, bacteriology or underlying cause. Attention has not been given to the clinical conditions which make up the causes of myocardial abscesses.

Such an abscess is considered relatively rare, in most instances as a metastatic manifestation of overwhelming sepsis and of more theoretical than of clinical significance.¹ Saphir stated that reports of abscesses in the myocardium are unusual, yet there seems to be no question that they occur quite often. As a matter of fact, he added, in every instance of premyocardial abscesses may be expected in the myocardium.

Since the introduction and widespread use of the sulfonamide compounds many successful results have been obtained in diseases for which the mortality was exceedingly high. Because the sulfonamide compounds have changed our entire outlook

TABLE 1—Causes in Twenty-Nine Cases of
Myocardial Abscess

toward many kinds of infection, it seems well to emphasize what diseases may cause myocardial abscesses. The myocardium, considering the character of its work, is the basic structure of a very durable organ, probably the toughest in the body. Various terms are used to designate how the infecting organism is conveyed to the heart muscle, such as sepsis, septicaemia, bacteremia, pyemia, staphylococemia and metastatic abscesses. The localization of abscesses in the lungs and kidneys is quite common in such conditions with a wide hematogenous spread. Abscess formation in the myocardium is less common and perhaps indicates a more virulent organism or a wider spread or both.

In the autopsy material at the Cook County Hospital, 29 (0.2 per cent) cases of myocardial abscesses were noted in 14,160 autopsies during the period from 1929 to 1942. At the Boston City Hospital 31 cases were noted,¹ while at the Michael Reese Hospital there were 32 (0.56 per cent) among 5,626 autopsies.² This report is based on a study of the 29 cases that came to autopsy at the Cook County Hospital.

BACTERIOSCOPY

Only one report¹ has bacterioscopic data available in 26 of its 31 cases. Staphylococcus aureus was responsible in 20, Streptococcus pneumoniae in 2, Streptococcus viridans in 2, Streptococcus pyogenes in 1, and the meningococcus in 1. In my cases the bacteria responsible were isolated in 28 of the 29 cases. Staph aureus or albus in 23, Streptococcus hemolyticus in 2, the pneumococcus in 2, and Strep viridans in 1. The organism mainly responsible is Staph aureus. It is a deadly organism once it enters the blood stream. This bacterium, of course,

low virulence and wide distribution, is usually a secondary invader, as it leads a saprophytic existence on the skin and mucous membranes of the body. Regardless of its apparent innocuity, it is exceedingly dangerous. The most insignificant point of infection may allow the staphylococcus to invade the blood stream, resulting in a very serious or fatal outcome owing to the formation of abscesses in one or many organs of the body.

addition to foci of necrosis, which are apparently the result of lodgment of small bacterial emboli in minute vessels or capillaries.

During this period 252 cases of bacterial endocarditis (34 acute and 218 subacute) were observed among the total number of cases in which necropsy was performed. These 8 cases referred to represent only 3 per cent of all the cases of bacterial endocarditis that came to autopsy. From the stand-

CAUSATIVE FACTORS

The causes of abscesses in the myocardium have not been mentioned previously. For this reason, and mainly because two thirds of these diseases are now amenable to chemotherapy, it seems well to emphasize them. Among the 29 cases 8 (27.5 per cent) were due to bacterial endocarditis and 7 (24.1 per cent) to acute osteomyelitis (table 1).

Bacterial Endocarditis—Myocardial changes have been frequently noted and stressed in cases of acute and subacute bacterial endocarditis. Clawson⁴ reported a greater frequency of abscesses in this than in any other form of endocarditis. Saphir⁵ noted that typical abscesses were often present in

point of frequency and present ability to cope with bacterial endocarditis myocardial abscess due to this cause is of little importance.

Acute Osteomyelitis—The surprising finding is that acute osteomyelitis may be more severe on the myocardium than bacterial endocarditis. A total of 80 patients with acute osteomyelitis came to autopsy or of which number 7 (8.7 per cent) had abscesses in the myocardium. Both diseases seem to affect the young especially males more frequently than females. The average duration of symptoms in those with bacterial endocarditis was 85 days while in those with acute osteomyelitis it was 75 days. The difficulty in diagnosis was equally great in the two groups and the staphylococcus was the common offender. However it is the great difference in response to present treatment that needs to be stressed. Whereas

⁴ Clawson B. J. Myocarditis. *Am Heart J* 1:1 (Oct) 1925.
⁵ Saphir Otto. Myocardial Lesions in Subacute Bacterial Endocarditis. *Am J Path* 11:1-5 (Jan) 1955.

bacterial endocarditis is seldom cured by the sulfonamide compounds, acute osteomyelitis is and can be cured by one of these drugs or by surgery, or by a combination of the two

Miscellaneous Infections—These include cases of myocardial abscess resulting from cellulitis, acute tonsillitis and pneumonia (table 4). In 13 of the 15 cases, chemotherapy or surgery or both as employed today might possibly have altered the outcome. This is becoming more apparent every day in cases of staphylococcemia. Besides the 252 cases of bacterial endocarditis and the 80 of osteomyelitis, there were 50 cases of septicemia or pneumonia, which made a total of 382 such blood stream infections. Myocardial abscesses were present in 29 (7.5 per cent).

COMMENT

This study of autopsies on patients with myocardial abscesses serves only to emphasize the importance of the underlying infection and to recapitulate the potential severity of so-called minor surface infections. Little can be added to the subject of bacterial endocarditis. However, an aspect of acute osteomyelitis is revealed which has not been mentioned previously. It should be looked on with the same view that the physician looks at bacterial endocarditis, as an extremely serious and fatal infection.

Although there is disagreement on the treatment of acute osteomyelitis, there is no question that it can be treated well if the diagnosis is made early. Grasso⁶ contends that it is not a primary disease of the bone but a localization of general septicemia or septicopycemia and should be treated as such. Key⁷ advocates early operative treatment, while Wilson⁸ holds that the surgeon should not be stampeded into an expedient operation simply because an abscess develops within the substance of a bone of a patient with septicemia. The mortality from septicemia associated with bone infections can be considerably reduced if sulfathiazole is employed in conjunction with relatively early adequate surgical drainage of the local lesion.⁹ Results obtained at Duke Hospital in the treatment of acute osteomyelitis with staphylococcic septicemia suggests that, with the exception of sulfathiazole, the sulfonamide compounds are contraindicated.¹⁰ Wilensky¹¹ stated that in actual practice the treatment of osteomyelitis with one of the sulfonamide compounds has not produced the startling results obtained in some other conditions, notably pneumonia. The results have been relatively good in the phase of general infection (bacteremia).¹² Mahorner and Crain¹³ feel that the important features responsible for the higher mortality are unjustified emergency operations without proper preoperative care and failure to reestablish preoperatively a normal physiologic state by fluid and electrolyte replacement and blood transfusions. The report of Hoyt, Davis and Van Buren¹⁴ confirms Grasso's contention, in 8 cases of acute staphylococcic osteomyelitis in which treatment with sulfathiazole without operation had been given, the end results were perfect, the bacteremia, as evidenced by positive blood cultures, was controlled by the administration of sulfathiazole without incision and drainage of the local abscess.

Whatever the outcome of the controversy on the treatment of acute staphylococcemia, it can safely be said that the introduction of the sulfonamide compounds has renewed and sustained great interest in the entire subject, with definitely improved results. Regardless of the cause of the staphylo-

coccic bacteremia, sulfathiazole appears to be the best therapeutic agent available at present for this type of infection, and it can be administered with a reasonable degree of safety.

SUMMARY

Abscesses in the myocardium are rare, as only 29 cases (0.2 per cent) were noted in a series of 14,160 autopsies at the Cook County Hospital. In itself it is not important, but it places proper emphasis on the significance of the underlying infection. The staphylococcus was the common offender in 23 cases (79.3 per cent). Among these cases bacterial endocarditis and acute osteomyelitis were found to be the main underlying diseases. The latter, along with such causes as cellulitis, acute tonsillitis, pneumonia and mastoiditis, are now more amenable to treatment, especially with sulfathiazole. The causes of myocardial abscess, particularly acute osteomyelitis, should be viewed in the same light as bacterial endocarditis, but with a greater degree of optimism, for with early diagnosis and proper treatment a favorable outcome is the end result.

TARGET CELLS IN POSTVACCINAL JAUNDICE

LIEUTENANT I. J. GREENBLATT

SANITARY CORPS, ARMY OF THE UNITED STATES

and

MAJOR GEORGE KAPLAN

MEDICAL CORPS, ARMY OF THE UNITED STATES

In 1937 Haden and Evans¹ described red blood corpuscles shaped in the form of a "Mexican hat" or a "sugar loaf." They claimed that these cells occur only in sickle cell anemia. A year later Barrett,² in an extensive study, showed the presence of these bodies (which he named "target corpuscles") in such varied conditions as obstructive jaundice, a "hypochromic" group of anemias in which the color index was not more than 0.8, steatorrhea, and following splenectomy. An interesting case of erythroblastic anemia in a young adult with target cells was described by Dameshek.³ In a more recent paper Singer, Miller and Dameshek⁴ discussed hematologic changes following splenectomy in man with particular reference to target cells and their physicochemical behavior.

THE TARGET CELL

In Wright's stained preparations, these red cells may vary from 7 to 10 microns in diameter. A small central mass of hemoglobin surrounded by a clear area, which in turn is circumscribed by an additional ring of hemoglobin, makes up the picture of the target cell. Often there is an apparent bridge between the central mass and the peripheral ring of hemoglobin (fig. 1). It is the position of the bridge. This can be readily demonstrated in the dark field. Barrett's² comparison with a "squat collar button" compares more favorably as a model for the description of these cells rather than the "Mexican hat" or "sugar loaf." In all our cases a "heparinized wet preparation" of venous blood was examined with the dark field microscope. The target cells were easily demonstrated in every instance. Here a more typical target effect can be observed (fig. 2).

We are in agreement with the observations of Barrett² and Daneshick³ as to the increased resistance of target cells to hypotonic saline solution. In 2 of our cases the actual blood smear count totaled as high as 40 per cent target cells. In 1 of these cases hemolysis was not complete in dilutions as low as 0.14 per cent of saline solution. Normally, hemolysis as

Fig 1—Appearance of target cells oil immersion

given by Santord⁴ is complete at a concentration of 0.32 to 0.34 per cent. In 73 per cent of our cases a definite increase of resistance to hypotonic salt solution was noted.

From June to September 1942 22 patients with postvaccinal (yellow fever) jaundice were admitted to the Medical Service of Camp Stoneman Station Hospital. In a routine blood smear of the very first patient with jaundice a high percentage of target cells was seen. Repeated blood smears from this patient continued to show these bizarre cells. All of our subsequent postvaccinal icteric patients were followed in a like manner

Fig 2—Appearance of target cells oil immersion dark field

and showed a similar pattern. These cells diminished in number as the icteric index decreased. However, a parallelism did not exist between the number of target cells and the severity of the icterus. When the icteric index became normal, few or no target cells were found. The smears also showed

varying degrees of macrocytosis, which has been commonly observed in jaundice in the past.

In a special survey conducted by the Surgeon General's Office⁵ a thorough investigation of the outbreak of jaundice in the Army was made. This included studies of liver function, kidney function and bile pigment excretion along with the usual laboratory procedures. Our findings in this respect are similar to that given by the Surgeon General and are therefore omitted from this report.

COMMENT

The origin of target cells is not within the scope of this report. The explanation of the aforementioned investigators as to the mechanism of the increased resistance of these corpuscles (target cells) can best be stated by quoting Barrett: "The target cell is thinner than the normal red cell and thus could imbibe more water before bursting (hemolyzing) in hypotonic solutions or salt."

It is our belief that target cells are more prevalent than heretofore recognized.

SUMMARY

- 1 Twenty two cases of postvaccinal (yellow fever) jaundice were studied.
- 2 An unusually high percentage of target cells in circulating blood in these cases has been found.
- 3 An increased resistance of the red cells to hypotonic salt solution was shown by 73 per cent of the cases.
- 4 The use of a heparinized preparation of venous blood with the aid of the dark field microscope offers an excellent means of studying these cells.

ACUTE NEPHROSIS COMPLICATING TWO DAY ARSENIC AND FEVER THERAPY FOR EARLY SYPHILIS

EVAN W. THOMAS, MD, GERTRUDE WEYLER, MD, MAX SCHUR, MD, AND WILLIAM GOLDRING, MD, WITH THE TECHNICAL ASSISTANCE OF NANCY EGGLESTON, M.S., NEW YORK

A one day treatment for early syphilis has been reported by Rose, Simpson and Kendall.¹ They employed artificially induced fever for ten hours in combination with mapharsen from 120 to 240 mg in the treatment of 23 patients. The only evidence of intoxication reported for these patients was transient increase in serum bilirubin or mild observable jaundice.

We have administered a two day treatment to 48 patients, consisting of two intravenous injections of mapharsen of 100 mg and 60 mg on the first day followed on the second day with two injections of 60 mg each and artificially induced fever to about 105.8 F for seven hours.

This report is concerned with 4 patients of our group who developed acute nephrosis. The clinical course of all 4 is shown graphically. An additional 4 patients developed severe albuminuria and azotemia or brief duration without fixed specific gravity of the urine. All recovered from the acute episode.

The absence of significant evidence of dehydration and the prompt loss of renal concentrating capacity in the 4 cases reported in the accompanying charts indicates that the azotemia was due to severe intrinsic renal damage rather than to hemoconcentration. The incidence of this renal complication in our group was 83 per cent. The chief subjective symptoms of our patients were nausea and vomiting. One patient was semistuporous for about twelve hours. Two had anuria or about twenty-four hours duration followed by oliguria persisting for a week or more. The other 2 had definite oliguria, but they would have been overlooked if daily urine analyses and repeated blood chemistry tests had not been done routinely.

As far as we know renal damage has not been reported for patients treated intensively with mapharsen alone. Large numbers of patients have now been treated with massive arseno-

6 Surgeon General's Report, The Outbreak of Jaundice in the Army, J. A. M. A. 120: 51 (Sept. 5) 1942.

5 Todd, J. C. and Sanford, A. H. Clinical Diagnosis by Laboratory Methods, ed. 9. Philadelphia: W. B. Saunders Company, 1942, p. 320.

therapy² but we have found no report of serious acute renal damage. In a series of 280 patients treated for early syphilis at Bellevue Hospital in a period of six to ten days with a total of 0.66 to 1.2 Gm of mapharsen alone no renal damage resulted. Seventy-three patients in this series had two injections of 100 mg of mapharsen daily for six days. Among 773 patients with early syphilis treated at Bellevue Hospital in a period of six to ten days with combined mapharsen and fever induced by typhoid vaccines, 1 had a transient hematuria with no azotemia. Albuminuria developed in many of the patients in this group during the days they received typhoid vaccine but there was no evidence of serious kidney damage. It is evident, however, that the combination of mapharsen with electropylrexia prolonged over six hours may cause acute kidney damage.

REPORT OF CASE

For the sake of brevity a detailed case history of only 1 patient is given. Laboratory findings of 4 are shown in the charts. Patient A. B., shown graphically in chart 1, was a Negro woman aged 21. She was admitted to Bellevue Hospital on Nov 10, 1942, the diagnosis was secondary syphilis. The urine on admission was normal with a specific gravity of 1.030. The blood nonprotein nitrogen was 34 mg per hundred

cc intravenously at 3 p m, and, on November 13, seven hours of artificial fever at 105.8 F, 0.06 Gm of mapharsen thirty minutes after the temperature reached 105 F and 0.06 Gm of mapharsen two hours before the cabinet was opened. During the fever session she received 53 Gm of sodium chloride and 3,000 cc of water. There were no complaints

Chart 1—Course in case 1

cubic centimeters, the blood pressure 110 systolic and 80 diastolic. The hemoglobin was 90 per cent (Sahli), the red blood cells 4,200,000, the white blood cells 8,150 with 45 per cent polymorphonuclear cells, 41 per cent lymphocytes, 1 per cent monocytes, 2 per cent myelocytes and 1 per cent eosinophils. Antisyphilitic therapy consisted on November 12 of 0.1 Gm of mapharsen intravenously at 8:30 a m and 0.06 Gm of maphar-

Chart 2—Course in case 2

Chart 3—Course in case 3

during the treatment. She vomited once. The blood pressure after the electropylrexia was 100/72.

On the day following the artificial fever the nonprotein nitrogen content of the blood was 35 mg per hundred cc, the blood chlorides 600 mg per hundred cc, and the blood urea 30 mg per hundred cc. Examination of the urine showed a specific gravity of 1.020, severe albuminuria and many granular casts.

She vomited frequently for the first three days following the fever therapy and then once a day for the next three days. The fourth day after treatment she voided no urine. On this day the nonprotein nitrogen content of the blood was 175 mg per hundred cubic centimeters. The following morning 75 cc of urine was obtained by catheter. The urine specific gravity was 1.010. It contained definitely increased protein, occasional granular casts and 6 to 8 red blood cells per high power field. The patient was semistuporous. There was no edema; the retinas were normal; the blood pressure 138/76. The blood nonprotein nitrogen was 225 mg per hundred cubic centimeters, the urea 304 mg per hundred cubic centimeters and creatinine 6 mg per hundred cubic centimeters. The hemoglobin was 70 per cent; the red blood cells 3,680,000, the white blood cells 15,000 with 62 per cent polymorphonuclear cells, 22 per cent lymphocytes and 16 per cent monocytes. The carbon dioxide combining power of the blood was 32 volumes per cent. She was given an infusion of 2,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride to which 5 Gm of sodium chloride was added. That afternoon she voided 150 cc of urine. In the next two days she was given similar infusions. Beginning with the third day, clinical improvement was rapid. The

Chart 4—Course in case 4

urinary output gradually increased and on the eleventh day after the fever treatment it was normal.

On the sixth day after treatment a catheterized specimen of urine showed 1 plus protein and 2 to 10 red blood cells per high power field. Until the eighteenth day after fever therapy there was a faint trace of protein and occasional red blood cells in the urine. Fixed specific gravity at 1.010 persisted until the patient was discharged on the twenty-seventh day after treatment. Renal function tests showed a maximum specific gravity of 1.015 and a maximum dilution of 1.010 on the twentieth and twenty-sixth days. On the eighth day the standard urea clearance was 2 cc per minute. The maximum urea clearance on the twelfth day was 97 cc per minute and on the eighteenth day 553 cc per minute. On the twenty-sixth day the standard urea clearance was 346 cc per minute. The phenolsulphonphthalein excretion for two hours was 28 per cent on the twentieth day after fever treatment and 581 per cent on the twenty-sixth day.

The nonprotein nitrogen content of the blood and the blood urea remained very high until the tenth day after treatment. Thereafter they gradually fell becoming normal in about three weeks after the treatment for syphilis.

On Dec 10 1942 the patient was discharged. Her blood pressure was 100/60. On Jan 7, 1943 the blood nonprotein nitrogen was 27 mg per hundred cubic centimeters and the urine was normal with a specific gravity of 1.024.

SUMMARY

Forty-eight patients with early syphilis have been treated with mapharsen and artificially induced fever.

Of this group 4 patients, promptly after treatment, developed an acute renal lesion with severe functional impairment. All patients recovered from the acute episode.

While no speculation has been attempted, the complication appears to be an acute nephrosis induced by the combination of arsenic and prolonged artificial fever.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PURSUANT TO THE ACTION TAKEN BY THE COUNCIL AT ITS LAST MEETING (J. A. M. A. 121:838 [March 13] 1943) THE COUNCIL IS WITHHOLDING FROM THIS COLUMN STATEMENTS ON TESTS AND STANDARDS ACTIONS, USES AND DOSAGE OF NEWLY ACCEPTED DRUGS WHICH MIGHT BE OF INTEREST TO THE ENEMY. THUS SUCH STATEMENTS FOR SUCCINYL SULFATHIAZOLE ARE OMITTED UNTIL A FUTURE DATE. THEY WILL APPEAR IN THE COUNCIL PUBLICATION NEW AND NONOFFICIAL REMEDIES AND MAY BE OBTAINED FROM THE COUNCIL OFFICE ON REQUEST.

SATURDAY, JULY 17, 1943

FEASIBILITY OF BACTERIAL WARFARE

The Geneva Disarmament Conference of 1932 considered bacterial warfare serious enough to prohibit its use. This action contributed to the popular fear of pathogenic micro-organisms as effective military weapons. To allay this fear come two timely reprintings of the classic paper by Col. Leon A. Fox¹ of the U. S. Army Medical Corps, which summarize the current opinion of military experts.

Threatened introduction of new weapons or methods of warfare has often had to overcome opposition based on ethical, religious or humanitarian grounds. The early use of gun powder had to overcome opposition of this type. Military history, however, teaches that a weapon has never been abandoned for such reasons unless displaced by more effective weapons or until adequate countermeasures have been developed. Military history also reveals that epidemics were often the determining factor in past wars. In many campaigns contagious diseases caused such great loss of life and such large numbers of non-effectives on both sides as to lead to a stalemate. In other campaigns great differences in the degree to which the two opposing armies reacted to such epidemics occurred.

The major military pests of the past have been the enteric fevers, typhus, bubonic plague and smallpox, with influenza, the pneumonias, malaria, measles, meningitis and syphilis playing a minor role. Popularly it is often assumed that these diseases would be particularly effective military weapons. However, fully virulent causative agents cannot be prepared in large quantities and cannot be introduced in adequate doses into the bodies of unprotected and nonimmunized enemy populations. The essential problem of bacterial warfare from an offensive point of view is therefore the problem of mass production of military pathogens and of devising safe and effective methods of inoculating the enemy. The whole group of enteric infections, for example, could probably never be successfully used as instru-

ments of warfare. Real epidemics of these diseases are traceable only to infected drinking water. While contamination of reservoirs and municipal storage tanks is militarily feasible, such contamination would be largely ineffective because of routine filtration or chlorination methods. Modern sanitary methods, therefore, should be adequate countermeasures against this type of bacterial warfare.

Among the respiratory infections, a number of maladies are serious enough to be effective if ways of using them can be devised. The two diseases of this group most frequently mentioned are influenza and meningitis. In neither disease could the infective agent be prepared in sufficient quantities, virulence or stability for military use. The meningococcus, for example, is so delicate that it rapidly dies when exposed for even a few hours to temperature much below that of the human body. The only feasible methods of introducing meningitis into opposite forces would be by human carriers. This would be hardly worth while, since any military aggregation of great size already has so many meningitis carriers (anywhere from 2 to 30 per cent) that the introduction of a few more carriers would be of little moment.

The use of insect borne diseases has also been repeatedly mentioned in the press, bubonic plague being the most thoughtful example. Possibly airplanes flying low could drop recently infected rats on opponent terrains. Even this, however, would probably not start an epidemic. Plague has been more or less endemic as a rodent disease on our own Pacific Coast for over a generation, yet there have been no local human cases in this region sufficiently numerous to be designated as epidemic. Only 6 cases of plague developed in 1924 among European troops stationed in the Punjab, in spite of the fact that 500,000 cases developed in the indigenous population.² Typhus also would be ineffective, since control of typhus is a question of local control.

Tetanus, gas gangrene and anthrax have been suggested as particularly effective military pathogens, since they are caused by resistant, spore forming bacteria capable of prolonged periods of viability without loss of virulence outside the animal body. These micro-organisms, however, do not produce epidemics even though they are of military interest as wound invaders. Effective methods of preventing and treating wound infections have been developed. Since wound invaders are omnipresent in nature, the indiscriminate distribution of a few additional wound invaders would not add appreciably to the present dangers of combat.

One of the commonest scares concerns the dissemination of "deadly bacterial toxins," of which botulinus toxin seems to be the pseudoscientific favorite. True,

¹ Fox, Leon A. *Mil. Surgeon* 90:563 (May) 1942, reprinted in *J. Lab. & Clin. Med.* 28:539 (Feb.) 1943.

² Pentler, C. F. *Some Thoughts on Bacteriological Warfare*, Graduate Thesis, Department of Biology and Public Health, Massachusetts Institute of Technology.
³ Gill, C. A. *The Genius of Epidemics*, London: Baillière Tindall & Co., 1928.

"an airplane can carry sufficient (botulinus) toxin to destroy an entire city," provided a carefully measured lethal dose of this toxin is administered orally, subcutaneously or intrarectally to each inhabitant of that city. The release of food materials contaminated with tremendous amounts of this toxin might conceivably cause a wholesale local destruction of rodents and sparrows. At most the number of human casualties would be negligible. Bacterial toxins like bacteria are readily destroyed by heat and are therefore inactivated by cooking. They are wholly unsuited for use in shrapnel or other projectiles.

Bacterial warfare is often extended in popular literature to include the use of boll weevils, corn borers and other agricultural pests. Most of these pests, however, take several years to propagate and invade a sufficient terrain to be effective economically. This would violate one of the fundamental laws of military science, since it might merely interfere with postwar economics, reducing the ability of a conquered nation to pay indemnities.

Summarizing his argument, Colonel Fox concludes that there are 'practically insurmountable technical difficulties preventing the use of biological agents as effective weapons of warfare.' In this he confirms the previous opinion of numerous German bacteriologists, who, five years before the first war, were assigned the task of suggesting safe and effective weapons of bacterial warfare. Ehrlich, for example, replied that 'nothing [he] could suggest would be of more than a nuisance value to the enemy and might even be a source of danger to our own troops.'⁴

It is hoped that Colonel Fox's paper will be as widely quoted in the popular press as have been the numerous frightening hypotheses that it contradicts.

PSYCHOANALYSIS AND THE SCIENTIFIC METHOD

In 1928 the late Dr. Joseph Jastrow¹ declared that the Freudian movement was rejected by the medical profession as unorthodox. "Its entire history is unfortunate," he said. "It was born in the clinic—an unfortunate birthplace for any doctrine with so wide and so personal an application, it was reared in distracting controversy, it traveled on the vise of psychoanalysis—a procedure as open to abuse as any narrow cult, and more so." A vast literature on Freudianism and the psychoanalytic method, some of it bitterly derogatory, has appeared. Now, some thirty-seven years since the Freudian theory was first brought to the United States by an article published by Boris Sidis in the *Journal of Abnormal Psychology*, an unprejudiced opinion of Freudianism as a theory and psychoanalysis as an instrument is still difficult to secure.

The aim of psychoanalysis as Freud conceived it "was not to tell people unpleasant truths about themselves but to cure patients by giving the integrative powers of their rational and conscious personality an opportunity to deal with those psychologic forces which were excluded from their conscious mind."² The criteria for judging Freudianism as a scientific contribution must be the same as those employed in judging any other scientific discipline. The features which have caused the greatest disrepute to fall on psychoanalysis are, first, the self-imposed requirement of justifying psychoanalysis by the results of treatment and, second, the preoccupation of Freudians with sex. Other phases of medical science have not been forced to justify their recognition by the results of treatment, this attempt to cite 'cures' as vindication may have hampered the true function of psychoanalysis. Indeed, when the results of therapy have been analyzed by objective observers (e.g. Kessel and Hyman³), grave question as to the value of the psychoanalytic method in treatment has arisen. As far as preoccupation with sex is concerned, the strong motivating force of sex drives has never been doubted but it is questionable whether this affects human behavior as much quantitatively as has been commonly claimed by most psychoanalytic workers. Indeed, a recent application of psychoanalysis to the problem of the Negro⁴ suggests that sex blockages play a comparatively small part in their motivation.

Unique in psychoanalysis has been the requirement that those who wish to evaluate Freudianism must themselves be psychoanalyzed. Of lesser importance is the divergence of most of those in the field of psychoanalysis from the usual custom of the medical profession regarding the collection of fees from other members of the profession.

Psychoanalysis has a nomenclature and diction that have been characterized as an unintelligible jargon. True, mathematics, physics and chemistry employ special symbols. It should be possible to make the language of any science understandable, at least with the help of a dictionary. A sentence such as the following, however, from a recent article in the field of psychoanalysis is without value to the uninitiated and its real significance even to those actively working in the field may be questioned. "This ego-feeling cathexis in turn depends on the compatibility of the single element with the whole ego unity."

² Sigmund Freud 1856-1939 editorial J A M A 113 1-94 (Oct 14) 1939

³ Kessel Leo and Hyman Harold Thomas The Value of Psychoanalysis as a Therapeutic Procedure J A M A 101 1612 (Nov 18) 1935

⁴ Holloman Laynard L. On the Supremacy of the Negro Athlete in White Athletic Competition Psychoanalytic Review 30 157 (April) 1943

⁴ Manwaring W. H. Personal communication 1909

¹ Jastrow Joseph Relation of Medicine to Psychology J A M A 92 720 (March 2) 1929

Leaders in the field of psychoanalysis may easily meet some of the more serious criticisms. By abandoning unscientific procedures and by adapting itself to the rapid evolution of psychosomatic medicine as a specialty, freudianism will achieve greater scientific stature and fulfil more promptly its early promise of extending the borderlines of medical knowledge.

Current Comment

DETOXICATION BY LIVER EXTRACTS

In standardized and well controlled experiments on rats, Chamelin and Funk¹ found that extracts of whole liver reduced toxic action of sulfanilamide injected intraperitoneally in toxic quantities (400 mg per kilogram). The liver extract had the same effect on the toxic action of diethylstilbestrol in rats. They found also that in mice injected with a strain of *Streptococcus hemolyticus* the survival rate was higher when the sulfonamide was combined with liver extract than when the drug alone was given, in other words, the liver extract diminished the toxicity of sulfanilamide without impairing its bacteriostatic action. Others² have found that whole liver or liver extracts counteract chronic intoxication by sulfonamide drugs. Whole liver extract apparently reduces the toxicity of two substances widely different in chemical structure and pharmacologic action. Both the evidence and the mechanisms by which these effects are secured invite further study.

AFFILIATED HOSPITAL UNITS FOR CIVILIAN DEFENSE

In THE JOURNAL for June 26, page 606, attention was called to the fact that two hundred and fifty-one hospitals and medical schools have been invited by the Surgeon General of the U S Public Health Service to organize affiliated hospital units of the Emergency Medical Service of the U S Office of Civilian Defense. Already more than one thousand physicians and dentists have applied for association with these units. Members of the staffs of affiliated units are commissioned in the inactive reserve of the U S Public Health Service, generally with ranks equivalent to those of captain, major or lieutenant colonel in the Army. They remain on inactive status except when there is an emergency arising from an air raid or other grave wartime disaster. When called to active duty they then receive the pay and allowances of officers of equivalent grade in the armed forces. They are expected to furnish service only in their own or neighboring states, and their obligation ceases at the termination of the

present national emergency. The nature of the service is recognized by authorization to wear a lapel button which indicates that they have enlisted for emergency service. They do not wear a uniform until called to active duty and need not purchase one unless directed to do so when called to active duty. The Board of Trustees of the American Medical Association and the Directing Board of the Procurement and Assignment Service have authorized essential physicians to accept positions with these affiliated units. Some physicians have expressed the fear that acceptance of these commissions might involve them in a responsibility to the U S Public Health Service and might in some way encourage the acceptance by the profession of the proposed Wagner-Murray-Dingell bill. This is a misunderstanding. Those who become associated with affiliated units are under no obligation to serve in any other capacity, no matter what functions Congress may some day see fit to thrust on the U S Public Health Service. Duties of members of affiliated units are limited strictly to those which they have agreed to assume as a result of enemy action.

THE DOCTOR'S RESPONSIBILITY IN ABSENTEEISM

From a governmental agency engaged seriously in the war effort with employees who work under the rules and regulations of the Civil Service Commission comes a complaint that some physicians do not take with sufficient seriousness their responsibility in controlling unnecessary absenteeism. One of the rules of the Civil Service Commission concerns the number of days and the pay allowed as sick leave. A request for over three days' sick leave must be accompanied by a certificate from a physician. Absence from duty is not permitted because of a slight illness which would not prevent the performance of duty or endanger the health of others. Nevertheless, many employees are absent for three or more days and seem to be able to prevail on some physicians to write certificates. If these physicians knew that certificates which cover certain slight illnesses would not necessarily be honored they probably would not bother to issue them. In one instance just checked by the government agency concerned, a physician in Philadelphia issued a certificate to the effect that a worker was sick with gastroenteritis and was unable to work for a period of six days in the month of May, whereas investigation developed the fact that the person who submitted the certificate actually was working in another establishment on the dates stated and was attempting to obtain pay from two sources by requesting sick leave with pay from one of them. In the interest of the war effort and as a means of reducing excusable absence physicians should refuse to issue certificates except in cases that can undoubtedly be considered to be of a serious nature and where there is no question but that the illness would incapacitate the person concerned for duty.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

ARMY SPECIALIZED TRAINING PROGRAM FOR MEDICAL STUDENTS

The War Department has sent the following letter to the deans of all participating medical schools:

It is anticipated that training in medicine, dentistry and veterinary medicine under the Army Specialized Training Program will have been initiated by July 23 in all approved schools of medicine, dentistry and veterinary medicine, with the exception of the Woman's Medical College of Pennsylvania.

The assignment of enlisted men to the Army Specialized Training units at these institutions is until further notice, restricted to those who are currently enrolled in these schools, to those who have been accepted by them for entering classes in medicine and dentistry and to accepted preveterinary students who are members of the Enlisted Reserve Corps.

The present restriction of selection for the continuation of preprofessional and assignment for professional training under the Army Specialized Training Program to the enlisted men who have assured individual vacancies in approved schools, through their acceptance for a future entering class, is necessitated by the fact that the freshman classes have been filled for 1943, the first half of 1944 and, in a number of instances, for late 1944. If these accepted applicants are in or enter active military service they will be assigned to the Army Specialized Training Program for the completion of the prerequisite preprofessional training and subsequent timely transfer to the Army Specialized Training unit at the school by which accepted.

It is obvious, however, that the medical and dental schools cannot continue to fill their future freshman classes from civilian sources only. Many students contemplating or preparing for the study of medicine or dentistry will have been inducted into one of the armed forces before acceptance by an accredited school is possible. If the supply of physicians and dentists, not only to meet the requirements of the armed forces but also for postwar civilian needs, is to continue beyond those now in or accepted for professional training, appropriate steps must be taken by the Army and by the Navy to assure necessary preparatory studies by qualified individuals in the military service, with a view to subsequent professional training in medicine and dentistry.

In order that detailed plans may be made for such premedical and pre-dental training under the Army Specialized Training Program it is necessary that the War Department determine the number of Army trainees who may be assigned to Army Specialized Training units at medical and dental schools in future freshman classes. The program of the Army will require at least 55 per cent of the vacancies in medical schools and 35 per cent of those in schools of dentistry. No trainees other than as stated above, will be assigned to units at schools of veterinary medicine.

HOW MEDICAL STUDENTS WILL BE SELECTED

The purpose of this letter is to explore the possibility of a mutual agreement whereby carefully selected enlisted men not accepted as individuals by the individual schools of medicine or dentistry may be assigned to Army Specialized Training units thereat for professional training with a view to receiving the appropriate degree in medicine or dentistry and appointment as first lieutenants in the Medical or Dental Corps of the Army of the United States.

The procedures involved in the selection and training of the enlisted men whom you will be requested to train in medicine or dentistry may be outlined briefly as follows:

On entering the Army, the recently inducted soldier is given certain classification tests the results of which are entered on the record which accompanies him to the unit or installation in which he receives his basic military training, thirteen weeks in duration. Those with certain high scores will there appear before the Army Specialized Training Program field selection boards for determination whether they should be assigned to this program for training at the college level. The actual field of such training and the academic level at which training should begin will be determined at the classification and assignment unit to which the selected soldiers are first assigned (Specialized Training and Reassignment Unit returned to as a STAR Unit).

From the STAR unit candidates who are manifestly suitable for or interested in the study of medicine or dentistry will be transferred to an appropriate training unit to begin preprofessional instruction at the basic level. The preprofessional curriculum of the first two terms of twelve weeks each, is common to that followed by trainees tentatively selected for engineering studies, mathematics, physics, general chemistry, English and so on.

It is during the second term that the real selection for preprofessional training is made with a view to subsequent training in medicine or dentistry. Representatives of approved schools of medicine and dentistry will participate in this selection. It is on them that the War Department is depending for the most careful determination of the enlisted men who should continue training in preprofessional studies. Since premedical and pre-dental training per se, is of little value in the military service attrition must be held to the minimum. At this level the trainees not considered fully qualified especially as regards fitness and aptitude for and attitude toward the study and practice of medicine and dentistry and service as officers in the Medical or Dental Corps of the Army of the United States, may be considered for training in other fields.

The trainees selected for future training in medicine or dentistry begin, in the third term, their biologic studies. These continue through term IV and term V, the last term. Organic chemistry and psychology are added in the fourth and fifth terms. In these two terms eight semester hours are available for subjects selected by the institution based on the special aptitude and interest of the trainee. This will permit a brief refresher course in a modern foreign language for trainees who have had appropriate previous instruction. It has not been considered possible to include such a course as a prescribed subject throughout the five terms.

PROGRESS OF TRAINEES WILL BE CHECKED

The progress of the premedical trainee will be checked both by the usual faculty examinations and also by periodic nationwide tests. The enlisted men who satisfactorily complete the premedical curriculum will be considered available for transfer to Army Specialized Training units for further training in medicine or dentistry. Such assignments must necessarily be governed by timely regional vacancies. The Army trainee will not make application for matriculation nor will he be accepted individually for a vacancy reserved for the War Department. His fitness for the study of medicine or dentistry has been determined. If recommended at the completion of preprofessional training he will be academically qualified. If it is proved that he cannot continue satisfactory progress in his medical or dental studies, he will be relieved from the Army Specialized Training Program for assignment to other duties.

While it is felt that in the future the complete task of preparing physically qualified male students for the study of

medicine or dentistry will devolve principally on the Army or the Navy, it is certain that premedical and pre-dental students will continue to enter the military service at various academic levels. At the completion of their basic military training these individuals must be given serious consideration for the continuation of their preprofessional training and subsequent professional training under this program. The selection of these enlisted men for such training will be made at STAR units and must be conducted with the same care as, indeed with even greater care than, that applied to trainees whose complete collegiate training has been under either the Army or the Navy program. Separate curriculums have been arranged for such trainees.

CONTRACTS WITH WAR DEPARTMENT

Within the near future negotiations will be begun with your institution for a contract with the War Department for the training of enlisted men in medicine or dentistry under the Army Specialized Training Program. This contract will contain provisions whereby the school will agree to train the enlisted men currently enrolled and those who have been accepted by the school for certain entering classes. It will also stipulate that, for the freshman class of the academic session agreed on by you and the negotiation officer, and for subsequent entering classes, you will make available to the War Department a specified number of vacancies for Army trainees. The number desired by the War Department represents, is already stated, approximately 55 per cent of the first year classes in medicine, 35 per cent of those in dental schools. The Navy is, I understand, requesting 25 per cent of such vacancies in medical schools, 20 per cent in dental schools.

Because of the necessity of assigning Army trainees to fill these vacancies on a strictly numerical rather than on a name basis, no assurance can be given that individual students accepted by you for classes in which a definite number of vacancies have been reserved for the War Department will be assigned to the Army Specialized Training unit at your school. It is realized that such a policy will limit the personal selection of medical and dental students which has proved so satisfactory and successful in previous years. However, no plan whereby individual assignment to these units may be effected appears feasible.

The transfer of medical or dental trainees from one unit to another is not contemplated, except, of course, in the case of medical trainees who have successfully completed their training in the schools of the basic medical sciences. It is felt that such trainees may advantageously be transferred as individuals, and to this end it is requested that arrangements now in force between the deans of the various approved schools of medicine be continued.

The War Department and my division fully appreciate the wholehearted cooperation which has characterized the attitude of the medical and dental schools toward the Army Specialized Training Program. I feel confident that this radical departure from the admissions procedures previously in operation at your school may be effected without detriment to sound medical and dental education.

HERMAN BEUKEMA, Colonel, G S C
Director, Army Specialized Training Division

NEW HAMPSHIRE STAR UNIT SENDS TWENTY-FIVE STUDENTS TO YALE

Dr Bennett F Avery, dean of the School of Medicine at Boston University, and Dr H Houston Merritt, assistant professor of neurology at Harvard Medical School, visited the Specialized Training and Reassignment unit at the University of New Hampshire on July 2 to interview candidates for premedical, dental and veterinarian Army Specialized Training. The student soldiers had already been tested and classified by the STAR unit at the university as candidates for those branches of Army Specialized Training.

The New England schools of medicine are cooperating with the Army in the careful selection of medical, dental and veterinary trainees for further study in the Army Specialized Training. Dr Avery, Dr Merritt and Dr George H Smith,

assistant dean of Yale University School of Medicine, make up the medical committee chosen to meet with the STAR unit in the First Service Command.

Each month, or whenever a group of candidates is ready, this committee sends two representatives to the STAR unit. The doctors study preparatory and college records of qualifying trainees and interview them personally to determine personality and character. Students selected for dental and premedical Army Specialized Training are those who, in the opinion of the committee, will not only be useful to the Army as dentists and doctors but will qualify with the medical profession as dentists and doctors after the war.

Drs Avery and Merritt, when interviewed, agreed that through Army Specialized Training their profession would gain many valuable members who, as civilians, might never have been able to afford a college and medical education both because of lack of funds and because of their families' need of their immediate earnings. Under Army Specialized Training, premedical and medical students are paid by the Army while in training.

Col George A Pollm, commandant of the Army Specialized Training, Specialized Training and Reassignment and Reserve Officers Training Corps units at the University of New Hampshire, expressed satisfaction in the method evolved in the First Service Command for choosing candidates for Army Specialized Training, particularly for premedical training.

Twenty-five premedical students were sent from the STAR unit at the University of New Hampshire for Army Specialized Training at Yale University on July 1.

NEW BRIGADIER GENERALS

The War Department announced on July 1 that the President had recommended to the Senate, among others, that Col Joseph E Bastion, M C, and Col Percy J Carroll, M C, be given temporary promotions to the rank of brigadier general. Colonel Bastion was formerly chief of the medical branch of the Sixth Service Command in Chicago and was transferred to Battle Creek, Mich, to command the Percy L Jones General Hospital, succeeding in that position Brig Gen Norman T Kirk, who became Surgeon General of the Army on June 1. Colonel Carroll was born in Illinois and graduated from the Louis University School of Medicine in 1914. He was commissioned first lieutenant in the medical corps of the regular army on Sept 27, 1917 after having served in the medical reserve corps previously from Oct 23, 1915.

COUNTY MEDICAL SOCIETIES AND THE CLINIC AT FORT CUSTER

Representatives of fourteen county medical societies, and about 150 physicians, attended a clinic at Fort Custer, Michigan, on June 30, arranged by the army medical officers serving at the 1,500 bed station hospital. Col John G Slevin, Detroit surgeon, the commandant, said that the idea of a military hospital presenting a clinic day for civilian physicians was developed as a result of the curtailment of medical society meetings during the war, further, that a wealth of material is available in the larger military hospitals which, when presented to the highly qualified medical officers, fills a need in the community at this time for scientific instruction.

The medical clinic at Fort Custer was in charge of Lt Col Frank B Lusk, chief of the medical service at the station hospital and formerly professor of medicine at the Cook County Postgraduate School of Medicine, Chicago. The surgical service was in charge of Lieut Col Joseph W Gale, professor of surgery in absentia at the University of Wisconsin School of Medicine.

In the afternoon a clinicopathologic conference was held under the direction of Major Joseph M Looney, chief of the laboratory section at the station hospital and formerly director of the laboratory section at the Worcester State Hospital, Massachusetts.

NAVY

PROMOTIONS IN THE NAVY

The following medical directors in the U S Navy have received executive nomination for the rank of rear admiral, for temporary service, while serving as district medical officer as indicated to rank from June 25, 1943

Edward Urbane Reed 3d Naval District
George Carroll Thomas 11th Naval District
William Leak Mann Jr 13th Naval District
Joseph John A McMullin 5th Naval District
Richard Henry Laning 1st Naval District
Daniel Hunt 12th Naval District

The following lieutenants (HC) have been advanced to the grade of lieutenant commander (HC)

Carl A Setterstrom	Thomas E Kent
Allen F Bigelow	Jason H Barton
Abraham T Schwartz	Ervin C Eastman
Benjamin W Claggett	Charles P Hines
Benjamin E Irwin	Corliss P Dean
Edward G Dennis	Willie R Joiner
Walter H MacWilliams	George A Fox
Norman L Saunders	

CONVALESCENT PSYCHIATRIC CENTERS

Certain facilities at the U S Naval Convalescent Hospitals at Sun Valley, Ida, Ahwahnee, Yosemite National Park, and Glenwood Springs, Colo, are now being used for the care and treatment of patients who have combat or operational fatigue. These neuroses are considered amenable to treatment by means of group psychotherapy. The treatment program planned for these hospitals covers a maximum of four to six weeks for each patient, and it is hoped that the majority can be returned to duty.

NAVY PERSONALS

Rear Adm D G Sutton, MC, USN, has been reassigned to the Division of Inspections in the Bureau of Medicine and Surgery and as medical inspector, Eastern Area.

Rear Adm E C White MC USN has been reassigned as medical inspector in Central United States.

Lieut Comdr William A Morris formerly medical director at the Yonkers General Hospital New York, reported for duty in June at the Naval Air Technical Training Center in Chicago.

CIVILIAN DEFENSE

NEW RECOMMENDATIONS ON TREATMENT OF BURNS AND WOUND INFECTIONS

The Medical Division of the Office of Civilian Defense announced on July 10 that it has revised the pamphlet 'Treatment of Burns and Prevention of Wound Infections' to incorporate new techniques that have been developed within the last year. The recommendations in this pamphlet are based on recent directions of the Committee on Chemiotherapeutic and Other Agents and the Subcommittee on Burns of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Originally drawn up by these committees for the armed forces the recommendations have been modified to adapt them to the problems involved in the treatment of civilian casualties.

Recommendations for the use of sulfonamides are accompanied by the observation that these drugs must be used more cautiously in the treatment of civilian wounds than is necessary in the care of military casualties for the following reasons:

'The injured may include individuals of all ages and with various types of preexisting disease, instead of a selected group of healthy young men. The possibility of toxic effects is therefore greatly enhanced. Moreover, it is assumed that in civilian injuries hospitalization will be possible in a relatively short time, whereas in military operations such is not always the case. This usually makes it possible to postpone all consideration of chemotherapy until the injured have been hospitalized. It is then possible to administer sulfonamides with better safeguards and to consider such contraindications as other pathologic conditions or known sensitivity to individual drugs. The dangers of dehydration can also be better prevented or overcome under such circumstances.'

In a discussion of intra-abdominal wounds leading to perforation of the hollow viscera, the revised pamphlet advises sodium sulfadiazine as the drug of choice for parenteral administration which is considered preferable to oral therapy during the first forty-eight hours. Sulfanilamide was recommended in the previous edition. Concentrated solutions of sodium sulfadiazine are not recommended for subcutaneous or intramuscular routes but it is pointed out that weak solutions (0.5 per cent) may be used with little danger of sloughing of the tissues.

Special emphasis is placed on the danger of giving sulfonamide drugs to a patient who is not voiding normally (over 1000 cc per day).

Should circumstances require sulfonamide administration in the presence of inadequate urinary output the urine should be watched for evidence of renal damage and the dosage of drug adjusted so that a blood concentration as evidenced by daily determinations, not to exceed 10 mg per hundred cubic centi-

mers, is maintained. If further diminution of the urinary output occurs administration of the drug should be stopped immediately and fluids should be forced orally if possible, and by means of dextrose and water (5 per cent in sterile distilled water) intravenously if necessary. If anuria due to bilateral obstruction of the ureters develops ureteral catheterization and lavage of the renal pelvis may be required.

The emergency care of burns is outlined in this pamphlet as follows:

'Whenever casualties with extensive burns can be admitted to hospitals without delay and definitive treatment can be instituted promptly morphine sulfate 1/2 grain should be administered at the scene of the incident and no local therapy applied to the burned area except sterile gauze to exposed surfaces to prevent infection.'

The most notable change in the pamphlet is the withdrawal of the recommendation of the use of ointments or jellies containing tannic acid in the first aid treatment of burns. The new advice given is that when definitive care cannot be carried out within two hours the patient should receive sufficient morphine to relieve pain (not less than 1/2 grain, except for patients with lung and bronchial damage the very old or the very young), and the burned surfaces should be covered with sterile boric acid ointment or petrolatum over which one or two layers of gauze of fine mesh (44) is to be smoothly applied. Over this dressing thick sterile gauze or sterile cotton waste is to be placed and the entire dressing is to be bandaged firmly but not tightly. Substitution of jelly containing 5 per cent sulfathiazole in water soluble base, which is supplied in the Office of Civilian Defense carrying case A for mobile medical teams, is permissible.

The discussion of definitive treatment of burns has been expanded to stress the necessity for administration of large amounts of plasma.

For patients with severe burns quantities up to 12 units or more may be required in the first twenty-four hours. To the patient in critical condition plasma must be given rapidly (as much as 500 cc in ten minutes may be necessary) and not allowed to flow drop by drop. It must never be administered by any other than the intravenous route. Syringe injection may be used. If facilities for hematocrit determinations are available the following general rule can be used for guidance regarding the amount of plasma required. For each point that the hematocrit is above 50 per cent cells at least 100 cc. of plasma should be administered. If clinically satisfactory results are not obtained with this dosage larger quantities should be given. A footnote points out that rapid administration of intravenous fluids may be dangerous to cardiac patients and that the physician's judgment will have to determine the amount as well as the rate of administration in such cases.

The pamphlet describes "open" and "closed" treatment for burns. The "open" treatment, which is now considered the treatment of choice and is especially recommended for treatment of burns of the hands, face, feet, perineum and genitalia, consists essentially of the application of boric acid ointment or petrolatum, with pressure dressings. Such dressings can often be left in place twelve or fourteen days.

The "closed" treatment, which is the tanning or eschar method, is particularly indicated in extensive "flash" or second degree burns of the trunk. This method is recommended only

if the following conditions are present: (1) If not more than twenty-four hours have elapsed, (2) if the burned area has not been grossly contaminated, (3) if strict surgical asepsis is employed in the preparation of the burned surface and (4) if coagulation is rapidly accomplished, i. e., by combined use of trinitic acid and silver nitrate. The method of tanning is described as in the original edition of the pamphlet.

In the new directions, additional emphasis is placed on masking of both the patient and his attendants in order to minimize the danger of secondary infection.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

Medical Schools Cooperate in Graduate Education

Under the auspices of the Wartime Graduate Medical Meetings arrangements have been made with fifty-five medical schools, through the Council on Medical Education and Hospitals, to participate in the teaching programs. The faculty members have already been designated from the University of Chicago, the University of Louisville, Emory University School of Medicine, Yale University and New York University.

The section committees of the Wartime Graduate Medical Meetings are engaged in conferences with commanding officers of service hospitals in their areas, selecting subjects, dates and teaching personnel for graduate courses. A recent directive was issued from the Office of the Surgeon General of the Army calling attention of commanding officers to this educational project and urging their cooperation and active participation.

PROCESSING PHYSICIANS IN THE FIELD

New instructions have been issued by the Officer Procurement Service and the Procurement and Assignment Service concerning the recruitment of physicians.

All available physicians are mailed invitations to seek commissions by the Procurement and Assignment Service. The invitation should be marked by the physician, indicating his choice of service, returned to the state chairmen, Procurement and Assignment Service, and forwarded to the appropriate agency. All requests for army appointments, including the Army Air Force, will be turned over to the Officer Procurement Service for processing and completion of the application.

The director of Naval Officer Procurement Service will handle requests for appointment in the Navy. Recent memoranda to the Officer Procurement Service stress urgent need for additional medical officers for the Army and describe techniques to be employed.

SALE OF PENICILLIN RESTRICTED

The War Production Board has issued allocation order No. M-338 which states that on and after July 16 no supplier shall use or deliver penicillin except as specifically authorized in writing by the War Production Board. The word "supplier" in this order means any person who produces penicillin, imports penicillin or purchases penicillin for resale as penicillin but shall not include any retail pharmacist, hospital or physician.

The order points out that the fulfillment of requirements for the defense of the United States has created a shortage in the supply of penicillin for defense, for private account and for export.

MATERNITY CARE FOR WIVES OF ENLISTED MEN

More than three fourths of the states have received approval by the Children's Bureau, Department of Labor, of programs for medical and hospital maternity care for wives of men in the four lowest pay grades of the armed services. Secretary of Labor Perkins reported on July 2. Following approvals by the Bureau, funds for the specified services have been made available to thirty-seven states, the District of Columbia and Hawaii.

Plans for New York, California and Iowa also have cleared the Bureau. Secretary Perkins said "When the funds for the

year beginning July are forthcoming, New York, California and Iowa will be in a position to authorize maternity and infant care for the wives and babies of enlisted men in the fourth, fifth, sixth and seventh pay grades. Plans from the health departments of Alaska, Ohio and Virginia are before the Children's Bureau for consideration and with their clearance there will remain only nine states which have not made application for federal funds or submitted plans for their services. These are Colorado, Georgia, Louisiana, Massachusetts, North Dakota, Oregon, Pennsylvania, Tennessee and Texas."

When a state plan has been approved and federal funds have been made available to the state health department, a serviceman's wife living in that state may make application for complete medical care during pregnancy and childbirth and for six weeks after childbirth. She may also apply for medical care for her child to extend throughout the child's first year of life. To get such care, all that the wife needs to do is to fill out simple forms, which, if her own doctor is unable to furnish copies, she can get from the state health department.

PRISONERS OF WAR

The Prisoners of War Information Bureau, under the Provost Marshal General in Washington, D. C., is the government agency which keeps records of American prisoners of war and civilian internees and maintains contact with their next of kin. However, the National Red Cross Societies and other humanitarian organizations accepted by the belligerents under the Geneva convention provide the machinery for giving relief supplies and other aid to the prisoners and also serve as a means of contact between the prisoners and their relatives. It is the function of the protecting power (Switzerland in the case of the United States) to see that the Geneva convention is properly observed by the detaining powers. The carrying out of the provisions for sending parcels and relief to internment camps, and for exchanging information between prisoners of nations at war and their own countries, is a tremendous task. The chairman of the American Red Cross, Norman H. Davis, recently said that the parcels of relief for American prisoners of war in Europe are operating smoothly and that, despite difficulties which at times appear overwhelming, the Red Cross and governmental agencies have continued negotiations to open relief channels to our prisoners in the Far East.

The rights of prisoners of war and their obligations are covered by international treaties which have been negotiated during the last seventy years and which culminated in the Geneva convention in 1929, signed and ratified by forty-two nations.

A prisoner has the right to receive letters as well as to write them and to receive parcels of food, tobacco, clothing, comforts and books, also the right to a proper trial for any alleged infringement of camp discipline.

In Switzerland more than five thousand persons are employed by the International Red Cross Committee, most of them volunteers, endeavoring to carry out the provisions for sending parcels and relief for internment camps and for exchanging information between prisoners of nations at war and their own countries. The committee has a card index of twelve million cards, if news seems to move slowly to the families of prisoners of war, one should consider the amount of detail involved in the difficulties of transportation and the fact that a great many persons are constantly trying to improve this service.

OFFICE OF PRICE ADMINISTRATION

AMENDMENTS TO RATION ORDERS OSTEOPATHS, CONDENSED MILK, FATS, OILS AND HOSPITALS

The Office of Price Administration announced on July 2 that any medical practitioner authorized by the state in which he practices to prescribe all internal drugs is also authorized to certify that a person requires supplementary food rations for health reasons. Authority to make such certification was previously confined to doctors of medicine. OPA has now broadened the authority so that osteopaths in states which license osteopaths to prescribe all internal drugs may also prescribe supplementary food rations. Food rationing regulations provide that a person whose health requires more rationed food than his ration points permit him to buy may apply to his local board for necessary additional points. In some illnesses foods are prescribed in addition to drugs or medicines, or as a substitute for them. In some countries the work of ration boards in processing such applications has been much simplified through the voluntary help of the doctors themselves. By establishing panels to review all medical certifications and to advise the boards responsibility for issuing extra rations for health reasons has been kept on a professional level.

The Office of Price Administration under date of June 1 placed evaporated and condensed milk on the list of rationed products. These types of milk are added to the group of rationed foods containing meats and fats for which red ration stamps are needed, without any increase in the total number of points allowed for this group. One point is required for one 14½ ounce can or for two 6 ounce cans or for two 8 ounce cans. This means that the child may use 7 of his 16 points per week for his milk requirements in terms of evaporated milk, which allows slightly less than the equivalent of a quart of whole milk per day, and have 9 points remaining for his meat and fat requirements. An invalid or any other person whose health requires that he have more canned milk than he can obtain with the stamps in his War Ration Book II may apply at his local War Price and Rationing Board for additional points. The consumer must submit a written statement of a licensed physician showing why he must have more canned milk, the amount needed during the succeeding two months and why unrationed foods cannot be used instead. A supplemental allotment to acquire canned evaporated and condensed milk needed by a hospital to meet the dietary needs of its patients may be obtained on application to its local War Price and Rationing Board. It is understood that if the present method of rationing does not make evaporated milk available in all areas for infants and children some more effective method will be worked out.

The Office of Price Administration has issued an amendment to ration order number 16 (R O 16, amendment 25) which permits the use of rationed fats and oils for external therapeutic purposes. This includes the use of vegetable oils, such as cottonseed oil, for bathing newborn infants, for external application in skin diseases, for urethral injection or lubrication of urethral instruments, and for x-ray visualization. Such use of rationed fats and oils is defined as 'industrial consumption' and persons using these products for such purposes are classified as 'industrial consumers.' An industrial consumer engaged in the care and treatment of the sick and needing rationed fats and oils for this purpose may apply to his district Office of Price Administration for a certificate with which to acquire them. The procedure to be followed briefly, is as follows. The application should be made on form R-1605 to the district office. If the applicant is a hospital the district office will pass on the application by using the same method of computing allowances as the local boards use in computing allotments for industrial users, otherwise the application will be forwarded to the Washington office for action. If the applicant requires more than he would receive by the method of computation described, he should also submit form R-315 stating the reasons for such request. An industrial consumer to whom a certificate is issued for 'industrial consumption' of rationed fats and oils may use it only to acquire the foods for which application was made and may use those foods only for the purpose for which the application was granted.

For several months the Office of Price Administration and medical authorities have been studying the hospital problem with a view to developing a uniform procedure covering the granting of supplemental allotments for hospitals. Solution of the problem is believed near. In the meantime a provision in the regulations (section 116 of general ration order 5) should enable hospitals to obtain the necessary supplemental allotments so that patients need not suffer from dietary deficiency. This provision gives local boards authority to grant such allotments to meet the dietary requirements of patients living in and receiving care in hospitals whether or not such patients are on special diets. In determining the amount of the supplemental allotment of processed foods and the commodities covered by ration order 16, the local board will take into consideration the availability of fresh fruits and vegetables unrationed substitutes such as poultry and fresh fish and the physical facilities of hospitals to process and store such foods.

PUBLIC HEALTH UNDER HITLER

According to *l'Effort* of March 24, chocolate in which fish liver with vitamin A is incorporated is now manufactured in Marseilles exclusively for the Secours national and distributed to children in tablets of 30 Gm containing 250,000 international units each.

DNB of March 27 states that the fourth Swiss Medical Mission with its auxiliary staff has returned home. Like the previous missions it has served for three months in military hospitals in the East and done valuable service in treating and caring for our wounded. This medical mission too has gained valuable experience and conveyed new knowledge and ideas to Swiss medical science and research.

The Berlin correspondent of *Svenska Dagbladet* of March 3 reports that the German birth rate statistics for 1942 show a sharp decline in the birth rate and a smaller decline in the death rate. The surplus of births declined by 53.6 per cent.

In Germany, excluding the former Polish territory of Eupen and Malmédy, 1,238,845 children were born against 1,528,330 in 1941, that is 15.2 and 18.8 per thousand respectively.

The number of deaths, excluding the armed forces declined from 995,573 to 990,346 that is from 12.3 to 12.1 per thousand. The surplus of births in 1942 apart from military losses, was 248,499 persons against 532,757 in 1941. During 1942 607,021 marriages were concluded against 589,614 in 1941. In December the birth rate was slightly better than during the previous month, namely 14.3 per thousand and against 13.2 in November, but the December death rate was slightly higher and even higher than in December 1941.

In the protectorate the birth rate increased throughout last year the total figure for 1942 being 18.3 per thousand against 16.7 in 1941. The death rate also increased being as much as 15.3 per thousand last December against 13.9 per thousand for the year 1942 an extremely high figure considering the hygienic standard of the protectorate.

The *Donauzeitung* Rumana, on February 3 reports that the Bucharest registrar's office recorded a total of 11,089 births, 12,215 deaths and 10,432 marriages in 1942. The birth rate has risen by about 5 per cent and the death rate by about 8 per cent as compared with the previous year whereas there was a slight drop in the number of marriages as against 1940.

OFFICE OF WAR INFORMATION

MEDICAL NEWS LETTERS

The following item prepared by the Office of War Information has been approved for release by the Department of State.

The Office of War Information, in cooperation with the American Medical Association, has since July 1942 been preparing biweekly Medical News Letters for transmission to medical men and scientists abroad, where they are received with enthusiasm. Before the war, United States journals had wide circulation outside the country, and the lack of such material in foreign countries today is somewhat alleviated by these condensations from the journals, since shipping conditions do not permit transportation of heavy periodicals.

The Medical News Letters constitute straight scientific information service to physicians cut off from their quota of current news of medical progress, and the humane service they render redounds to America's advantage. For eager doctors, who are thus kept abreast of new developments and who would otherwise be left in the dark, are grateful to the United States for enlightenment.

The material, about 2,500 words of digests of current advances, is prepared by the abstracting staff of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and edited and printed by the Features Division of the Overseas Branch of the Office of War Information. It then goes to the State Department, which distributes it to the OWI outposts and diplomatic missions overseas.

The News Letters are sent by air to more than sixty areas, from Iceland to South Africa, including such remote points as Noumea and Madagascar. OWI regional outposts, when they receive the material, reproduce it in large quantities. In Ireland alone, for instance, 3,000 copies of the Medical Letters are circulated to Irish doctors and institutions, and in Sweden about 6,000 Science News Letters are now being distributed.

In English speaking countries they are printed as they stand in the medical journals of the area. In non-English speaking countries they are translated on the spot and reproduced in Swedish, French, Arabic, Chinese, Hindustani or numerous other foreign journals. If no journals exist, the letters are mimeographed and mailed to all the doctors and interested parties in the region.

That the Medical News Letters are welcome becomes increasingly clear as the file of dispatches conveying the appreciation and thanks of foreign scientists for the American effort to keep them abreast of current developments grows. These men express their gratitude not only for the Medical Letters but also for the other scientific information that the OWI is distributing. Science News Letters in the fields of astronomy, agriculture, genetics, biology, physics, geology, psychology and engineering are prepared, with the help of experts in each field, and delivered to many countries each month. This list is still growing. Ophthalmology, animal husbandry and veterinary medicine will be covered shortly.

Many illustrations could be given of the enthusiasm with which the News Letters are received. The following few will suffice to show the value of the project. A quotation from a letter written by a Swedish physician reads: "Please excuse my bad English. You can be sure that I am glad to have your Medical News Letter. When I saw it at first I had a glimpse of a sunray coming into this black night of isolation and almost hopeless fear that for so many years—yes, it seems like so many dark years—have been so heavy on our depressed minds."

A well known professor from the University of Finland, after expressing his gratitude, pointed out that the "sending of scientific information such as that embodied in the News Letters is a shrewd and effective way of reminding intelligent Finns

that the United States is a more enlightened and civilized country than Dr Goebbels would have people believe." Another Swedish dispatch said that "the Swedish medical men have long been accustomed to receive American medical journals and they have expressed great disappointment over their failure to arrive. The Medical News Letter fills a definite need, both psychologically, in making the Swedish medical men feel they still have contact with the democratic countries, and materially, in giving them information regarding the progress of medicine in the United States."

An interesting letter from a Moslem doctor in Syria who was furnished with a Medical News Letter reads in part: "The best way to love God is to love His creatures, and it is equally true that love of God is to relieve the ills of mankind. The credit of maintaining this service goes to American scientists, who during these difficult times are extending such a medical service, especially to this little known country."

Two Italian physicians in Eritrea took the trouble to write: "We very much appreciate the effort made to put us doctors in contact with medical progress after so long an interruption." The vice chancellor of Queen's University in Belfast described the Science News Letter as most interesting and said: "It is a very great pleasure to receive these papers, which I am circulating to our scientific departments, and they will be very much appreciated. Under present conditions it is far from easy for scientific workers in the United Kingdom to keep fully informed about the progress which their colleagues in the United States are achieving, and these papers will be read with the greatest interest. Perhaps you will kindly convey the sincere thanks of this university for the help which the Americans are so kindly rendering."

From distant Lourenço Marques in Portuguese East Africa, a communication arrived which reads: "Physicians and military men here are most anxious to keep abreast of developments in the United States, and many of the medical men have requested me to express their appreciation to the Office of War Information and the American Medical Association for the News Letters, which are being widely distributed throughout this area and receiving such favorable comment." And in Great Britain, which, despite the war, is keeping up progress in medicine and research, this item appeared in the *Medical Press and Circular* of March 24. It was headed "Medical Letters" and ran as follows: "Most of us are familiar with our own *Bulletin of War Medicine*, a publication which has proved of extreme value in the dissemination of the latest information on problems arising out of the war. The Office of War Information of the United States government is now providing a series of Medical Letters which are published fortnightly and issued in this country from the American Embassy in London. These letters, if informally, are most attractively presented. They consist of a series of condensed reports on various advances in the field of medicine, prepared by the American Medical Association, they are not specifically confined to war medicine, although this subject receives its full share of attention. One of the most interesting features comes under the heading 'What U.S. Doctors Are Talking About.' Altogether, these Letters, which so far as we know represent a very novel departure on the part of any government, are of the greatest interest and value. We would like to congratulate those responsible for their production most heartily. Incidentally, we trust that they will be continued after the war. It seems a pity that such an excellent idea should be restricted merely to these abnormal times, although the needs of the moment may be."

It could not be made more dramatically clear that the world over still look to America for light and progress.

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bills Introduced—H R 3087, introduced by Representative McGhee, Mississippi, proposes to amend the privileged communication statute of the District of Columbia so as to make it inapplicable to information obtained by a physician in professionally attending a patient in cases wherein the physical or mental condition of the patient is in issue. H R 3150 introduced by Representative Randolph West Virginia, proposes to amend the healing arts practice act of the District of Columbia to eliminate the requirement that an applicant, applying for a license without examination must have practiced the healing art under a license obtained in another jurisdiction for not less than two consecutive years immediately preceding the date of his application for his license in the District. As a substitute for this requirement, the bill would provide that the applicant must have practiced the healing art after the issuance of the license obtained in another jurisdiction for not less than one continuous year out of three years immediately preceding the date of his application for license in the District. This bill would provide too that the required one continuous year's practice may be either private institutional or governmental, or a combination thereof.

MEDICAL BILLS IN CONGRESS

Changes in Status—H R 997 has passed the House and Senate establishing a Pharmacy Corps in the Medical Department of the Army. As originally introduced this bill proposed to eliminate the Medical Administrative Corps and to substitute therefor a Pharmacy Corps. As enacted this legislation leaves intact the Medical Administrative Corps. H R 2936 has passed the House and Senate authorizing an additional \$200,000,000 for expenditure under the Lanham Act for the construction of community facilities. S 1250 has passed the Senate, repealing existing law under which the pay of persons in the military and naval service who are absent from duty on account of the direct effects of venereal disease due to misconduct is forfeited.

Bills Introduced—S 1277, introduced by Senator Thomas, Utah, proposes that the benefits of the United States Employees' Compensation Act be extended to all civilian officers of the United States, commissioned officers of the Coast and Geodetic Survey, commissioned officers of the regular corps of the United States Public Health Service and officers in the Reserve of the United States Public Health Service on active duty. S 1295 introduced by Senator Pepper, Florida, provides for the making of loans to war service persons on honorable discharge or honorable release from service to enable them to complete their education. Any war service person the bill provides while receiving educational training or the husband, wife, child or children of such person shall be eligible to receive any necessary medical attention or care at any hospital or medical institution wholly supported by the United States Government when facilities exist in such hospital or medical institution for furnishing such medical service or care. S 1320 introduced by Senator La Follette, Wisconsin, proposes that the Surgeon General of the Public Health Service shall provide on the request of state or local health authorities for the hospitalization treatment and subsistence in hospital facilities operated by the Public Health Service of persons registered under the Selective Training and Service Act who are found to be infected with venereal disease. Senator La Follette first offered this legislation as an amendment to H R 2935 the Labor-Federal Security Appropriation Act but the amendment was ruled out of order. S 1329 introduced (by request) by Senator George Georgia and H R 3176 introduced by Representative Rankin, Mississippi propose to regulate the furnishing of artificial limbs or

other appliances to retired officers and enlisted men of the Army, Navy and Marine Corps or Coast Guard and to certain civilian employees of the military and naval forces of the Regular Establishment. H R 3086, introduced by Representative Forand, Rhode Island, proposes to provide identification buttons for persons discharged from military or naval service due to physical defects not due to personal misconduct. H R 2939, introduced by Representative McMillan, South Carolina, proposes to provide a uniform allowance for members of the Army Nurse Corps. H R 3178, introduced by Representative Celler, New York, proposes to provide for the wartime care and protection of children of employed mothers.

STATE MEDICAL LEGISLATION

Alabama

Bill Introduced—S 328 proposes the creation of a board of medical technicians examiners and defines a medical technician as a person who, as a result of certain technical training (in a training school approved by the Council on Medical Education and Hospitals of the American Medical Association) or certain apprenticeship-instruction is engaged in the practice of standardized or experimental technical procedures covering any of the various departments of laboratory methods (urinalysis, hematology, bacteriology, parasitology, histopathologic technic, biochemistry and serology) the results of which are interpreted by a physician in the diagnosis of disease.

Bill Enacted—S 213 has become Governor's No 164 of the Laws of 1943. It authorizes the governing bodies of every state department, county, municipality, board, commission or subdivision of the state of Alabama to adopt and carry into effect a system of group life insurance and group hospitalization insurance or either, for the benefit of its employees.

Connecticut

Bills Enacted—S 253 has become chapter 332 of the Laws of 1943. It authorizes the state board of examiners for nursing to issue temporary licenses to certain properly qualified persons. H 312 has become chapter 366 of the Laws of 1943. It provides for an appropriation of \$50,000 for furnishing medical, hospital, nursing, obstetric and pediatric care to wives and children of service men when they are unable to purchase such care for themselves. H 1026 has become chapter 325 of the Laws of 1943. It authorizes a court, in certain circumstances to order the examination of an accused person to determine whether or not such person is suffering from a venereal disease and if the result of the test is positive to make such order as may be necessary for the detention and treatment of such person. The examination shall be conducted at the expense of the state. H 1312 has become chapter 311 of the Laws of 1943. It amends the law relating to the practice of chiropractic by eliminating therefrom the existing requirement that chiropractors show satisfactory evidence at the time of the annual renewal of their licenses that they have attended at least one of the two day educational programs conducted by the Connecticut Chiropractic Association, Inc. the subjects of such programs being under the supervision of the state board of chiropractic examiners.

Ohio

Bill Enacted—S 36 was approved June 3. It is an administrative procedure bill providing for uniformity of procedure in hearings and actions taken by administrative boards such as the medical board.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY FINDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITY THIS LAW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Dr Swartout Appointed Health Officer of Los Angeles County—On June 17 Dr Hubert O Swartout was appointed health officer of Los Angeles County. Dr Swartout has been acting health officer since the appointment of Dr Wilton I Halverson as state health officer (THE JOURNAL, February 13, p 530)

Herbert Evans Honored—Dr Herbert M Evans, Morris Herzstein professor of biology and director of the Institute of Experimental Biology, University of California Medical School, San Francisco, was guest at a dinner on June 4 given by members of the medical and other faculties of the university to mark his sixtieth birthday, which will be observed in September. The celebration was held at the Bohemian Club, San Francisco, under the chairmanship of Dr William J Kerr, San Francisco, professor of medicine at the medical school. Dr Evans was presented with an anniversary volume published by the University of California Press entitled "Essays in Biology," containing forty-eight scientific contributions from pupils, associates and friends representing the physiology of reproduction, docimology, nutrition and the history of medicine and science. Reports that the publication was planned before the war, and the participants are leading foreign and American workers in their respective fields.

DELAWARE

Rocky Mountain Spotted Fever—On June 24 the Delaware Board of Health, Wilmington, reported 2 cases of Rocky Mountain spotted fever in Cedar Creek and Little Creek townships. According to the New York Times, June 25, this brings to 4 the number of cases reported in the state during the previous two weeks. No cases were reported last year.

DISTRICT OF COLUMBIA

District Medical Election—Dr James N Grear Jr was chosen president-elect of the Medical Society of the District of Columbia at its annual business meeting on May 5 and Dr Fred R Sanderson was installed as president. Mr Theodore Wiprud is the secretary-treasurer. The annual scientific assembly will be held at the Mayflower Hotel, Sept 30 to Oct 2, 1943.

Fund for Psychiatric Aid to Children—The Loren B T Johnson Memorial Fund has been established by Mrs David S Barry Jr in honor of her father. The \$25,000 trust fund will be used for "the intensive and specialized care and treatment of children in connection with the special objectives of the Washington Institute of Mental Hygiene." Dr Johnson, who died in December 1941, helped organize the Washington Child Guidance Clinic and the Life Adjustment Center, which were later merged to form the Washington Institute of Mental Hygiene, now supported by community chest funds. Dr Winfred Overholser succeeded the late Dr Johnson as president of the mental hygiene institute.

ILLINOIS

Bicounty Defense Zone Health Department—The Fulton and McDonough counties have joined to establish the first locally directed bicounty defense zone health department in the state. The unit is under the full time supervision of Dr Edward L Hill Jr with headquarters at Macomb.

Chicago

Course on Wartime Nutrition—A postgraduate assembly on wartime nutrition will be sponsored by the Institute of Medicine of Chicago at the Palmer House, November 17-18. Details of the course, for which there will be no registration fee, will be announced later.

Dr Stewart Thomson Named Assistant Dean—Dr Stewart C Thomson, assistant professor of anatomy, Loyola University School of Medicine, has been appointed assistant dean of the school, succeeding Dr John G Powers, who plans to enter private practice. Dr Francis J Braceland, dean of the medical school, is now in the Navy. Dr Thomson has been a member of the faculty of Loyola since he graduated there in 1936.

The Capps Prize—Announcement is made of the Joseph A Capps Prize offered annually by the Institute of Medicine of Chicago for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. Competition is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1941 or thereafter. Manuscripts must be submitted to the Institute of Medicine of Chicago, 85 East Randolph Street, not later than December 31.

INDIANA

Mental Patients' Orchestra—So successful has been an experiment with an orchestra composed of inmates at the Indiana Hospitals for Insane that an additional program for the development of singing and dancing has now been undertaken, according to the state medical journal. The orchestra has grown from a group of 12 to 29. None of the inmates who agreed to try to learn to play musical instruments had had any previous experience. A campaign was conducted by the Michigan City News Dispatch to obtain instruments. The first appearance was before members of the board of trustees. Patients who previously had refused to study music became eager to do so. The 29 inmate-musicians at the time of this report had a repertoire of twenty-five pieces.

MICHIGAN

Changes in Health Officers—Dr Leonard C Bate, Staunton, director of the Iron County Health Department, was placed in charge of the unit in Ontonagon County, effective June 1. The central office of the two counties will be maintained in Staunton with a branch in Ontonagon.—Dr Clifford C Corkill resigned as head of the Menominee County Health Department, effective July 1, to enter private practice.—Dr Madeline M Donnelly has been named director of health district number 7 comprising Clare, Gladwin and Arenac counties, following the vacancy that occurred with the transfer of Dr Helen E P Lanting, Gladwin, to a similar position in the Shiawassee County health district.

Annual Report of Children's Fund—More than \$34,000 was expended by the Children's Fund of Michigan through various agencies, including donations of \$96,000 to seven war agencies, according to its fourteenth annual report recently made public and covering the year ended April 30. Of the original fund of \$10,000,000, which was later increased by more than \$2,000,000 by Senator James Couzens, more than \$7,500,000 remains. Both capital and earnings of the fund are to be applied in the field of child health and guidance over a twenty-five year period at the annual rate of about \$700,000. The largest contributions for the fiscal year, the report showed, were in the field of child health, with expenditures totaling \$337,039. In the field of health education \$10,650 was appropriated. The year concluded the second in which the Children's Fund subsidized the state department of public instruction to help it incorporate within itself a system of health education. Prior to the arrangement with the state department, the Children's Fund had for a number of years been financing a health education demonstration. The total expenditure for dentistry was \$144,757. Four counties, Grand Traverse, Leelanau, St Clair and rural Wayne, have completed health organization, one of the objectives of the fund, while Iron, Menominee, Mecosta and Osceola counties will soon complete their own programs, making a total of ten locations previously subsidized by the fund from which it will retire. Other donations to independent health agencies include the second payment of \$20,000 on an \$80,000 appropriation to the House of Good Shepherd in Detroit for a new hospital building. Under grants to war agencies, the report lists a \$50,000 donation to the War Chest of Detroit and a payment of \$32,500 on a \$65,000 pledge to the American Red Cross. A fund of \$10,000 was also set up late in the year to assist in the establishment of nurseries in schools to care for children of working mothers. Seven child guidance institutions received grants totaling \$110,607, including \$90,857 to the Children's Center, Detroit, which was created by the fund. An \$11,000 grant made annually for child guidance on a statewide basis will be discontinued, with the state taking over the appropriation next year. Thirteen recreational organizations received grants of \$38,050, and the Michigan Children's Aid Society, which cares for dependent children, received \$29,150. Research programs, including projects at both Wayne University, Detroit, and the University of Michigan Medical Center, received \$68,416. General administration costs totaled \$43,342.

NEBRASKA

The Eleventh Annual Assembly—The Omaha Mid-West Clinical Society will hold its eleventh annual assembly, October 25-29. Among the guest speakers and their subjects will be Drs. Eben J. Carey, Milwaukee, basic sciences, Sanford R. Gifford, Chicago, eye, ear, nose and throat, Cyrus E. Burford, St. Louis, genito-urinary, Jennings C. Litzberg, Minneapolis, gynecology and obstetrics, James E. Paullin, Atlanta, Ga., and Tom D. Spies, Birmingham, Ala., and Cincinnati, medicine. Harold G. Wolff, New York, neurology, Frank R. Ober, Boston, orthopedic surgery, Luther Emmett Holt Jr., Baltimore, pediatrics, and Raymond W. McNally, Chicago, and Robert Lee Sanders, Memphis, Tenn., surgery. A symposium on military medicine and surgery will be a feature of the meeting on Friday, October 29.

NEVADA

State Board of Medical Examiners—Dr. Robert P. Roantree, Elko, was reelected president of the Nevada State Board of Medical Examiners at a meeting on May 5 and Dr. George H. Ross, Virginia City, was chosen secretary-treasurer. Dr. Ross was named to succeed Dr. Richard A. Petty, Carson City, who resigned to enter the Navy.

NEW HAMPSHIRE

Broadcasts on Industrial Hygiene—The division of industrial hygiene of the New Hampshire State Board of Health is presenting a series of broadcasts on industrial health problems.

Dr. Frechette Granted Leave for Rehabilitation Work—Dr. Alfred L. Frechette has been granted a leave of absence as secretary of the New Hampshire State Board of Health, Concord, to engage in war rehabilitation work under the auspices of the U. S. Public Health Service. He left for his new activities on May 20. He has been with the state board since 1938, first as director of the division of venereal disease control and later as deputy secretary. In 1942 he was named secretary and executive officer of the board.

NEW YORK

Outbreak of Septic Sore Throat—*Health News* recently reported an outbreak of septic sore throat and scarlet fever involving over 50 students and faculty members of an upstate school. Tapioca pudding which had been allowed to stand overnight without refrigeration was served at a school lunch. It had been prepared by a woman cook who, after the outbreak, stated that she had "felt poorly" during the previous day or two and who on the day of the luncheon had gone home with a sore throat. The symptoms included fever, inflamed throat and swollen glands, and in a few cases there was a scarlet fever rash. Every one of the 55 patients had eaten the school luncheon regularly, while no illness was found among 14 pupils who had the noonday meal at home.

New York City

Dr. Oswald Avery Retires at Rockefeller Institute—Dr. Oswald T. Avery, a member of the staff of the Rockefeller Institute since 1913, has been made member emeritus of the institute. He has reached the retirement age. A graduate of Columbia University College of Physicians and Surgeons 1904, Dr. Avery was associate director of the department of bacteriology at the Hoagland Laboratory of the Long Island College Hospital, Brooklyn, from 1907 to 1913. His work in bacteriology and immunology of respiratory diseases had won for him the J. Mather Smith Prize, the John Phillips Memorial Medal and the Paul Ehrlich Gold Medal. In 1930 he was president of the Association of Immunologists and in 1933 of the American Association of Pathologists and Bacteriologists.

Annual Graduate Fortnight—"Disorders of the Digestive Tract" will be the theme of the sixteenth Graduate Fortnight of the New York Academy of Medicine, October 11-22. Following an address of welcome by Dr. Arthur F. Chace, president of the academy of medicine, Dr. Andrew C. Ivy, Bethesda, Md., will deliver the Ludwig Kast Lecture on "The Physiology of the Gastrointestinal Tract." On Friday the Wesley M. Carpenter Lecture will be delivered by Dr. Robert E. Leman, St. Louis, on "Parenteral Fluids and Food in Gastrointestinal Diseases." Other speakers on the program will include:

Dr. Harold G. Wolff, Emotions and Gastric Function
Dr. Edward B. Benedict, Boston, A Critical Review of Gastroscopy
Dr. Arthur W. Allen, Boston, Diagnosis and Treatment of Benign and Malignant Lesions of the Stomach
Dr. Harry Shay, Philadelphia, The Pathologic Physiology of Gastric and Duodenal Ulcer

Dr. Asher Winkelstein, Recent Advances in the Therapy of Peptic Ulcer
Dr. Rustin McIntosh, Disorders of the Gastrointestinal Tract in Children
Dr. William E. Ladd, Boston, Surgical Aspects of Congenital Anomalies of the Gastrointestinal Tract in Children
Dr. Ralph Colp, Postcholecystectomy Syndrome and Its Treatment
Dr. Allen O. Whipple, Recent Advances in the Surgery of the Pancreas
Dr. Jacob A. Barger, Rochester, Minn., Present Status of Regional Enteritis and Ulcerative Colitis
Dr. Winfield M. Firor, Baltimore, The Sulfonamides in Gastrointestinal Diseases
Lieut. Col. Thomas T. Mackie, M. C., A. U. S., Amebiasis and the Flagellate Diarrheas
Rene J. Dubos, Ph.D., Boston, Problems of Immunity to Bacillary Dysentery
Dr. William Osler Abbott, Wynnewood, Pa., The Management of Acute Intestinal Obstruction
Dr. William L. Watson, Treatment of Diseases of the Esophagus
Dr. Henry W. Cave, The Surgical Management of Certain Diseases of the Colon
Dr. Harvey B. Stone, Baltimore, Diseases of the Anus and Rectum
Dr. Frederick J. Stare, Boston, Nutrition in Medicine

Morning panel discussions will be held Tuesday, October 12, on "Emotions and Gastric Function" with Dr. Wolff as chairman. Friday, October 15, "Diagnosis of Gastrointestinal Lesions by Means of X-Ray and Gastroscopy" with Dr. Ross, Golden, New York, Tuesday, October 19, "Use of Sulfonamides in Gastrointestinal Diseases," Dr. Walter A. Bastudo, Friday, October 22, "The Commoner Diseases of the Anus and Rectum of Interest in General Practice" with Dr. Stone. There will be exhibits demonstrating the recent advances in the etiology, pathology, diagnosis, prophylaxis and treatment of disorders of the digestive tract and special demonstrations of fresh pathologic material. There will be a special exhibition of books on the subject. Afternoon clinics have been planned at various hospitals in the city.

NORTH CAROLINA

School of Physical Therapy Established—The medical school and the Woman's Coordinate College of Duke University, Durham, will open a school of physical therapy, September 27, with Dr. Lenox D. Baker, head of the Duke orthopedic service, as medical director. Miss Helen Kaiser, Cleveland, formerly president of the American Physiotherapy Association, will be the technical director. The school will be conducted at Duke Hospital and will give a nine months course of study and training. Candidates must satisfy one of the following requirements: two years or sixty semester hours of college, including courses in physics and biology, graduation from an accredited school of physical education or graduation from an accredited school of nursing. Owing to the war demands for nurses at this time, candidates from the latter group are not especially desired. A number of scholarships are given for the benefit of women interested in this field of work. Miss Kaiser graduated in the course of physical therapy of Harvard Medical School, Boston, and served there as assistant instructor. She served three years as chief physical therapist of the Detroit Orthopaedic Clinic. She reorganized and established the physical therapy departments of the Woman's Hospital and the Mount Sinai Hospital, Cleveland.

TEXAS

University News—Leslie L. Lumsden, New Orleans, epidemiologist, medical director U. S. Public Health Service, retired, has been made lecturer in epidemiology at the University of Texas Medical Branch, Galveston. The regents of the University of Texas have accepted legislative authorization to incorporate the Texas Dental College, Houston, into the University of Texas health program. Fred C. Elliott, D.D.S., has been appointed by the regents to continue in charge of the institution which will be known as the University of Texas School of Dentistry. Dr. Eric Ogden, associate professor of physiology at the University of California Medical School, San Francisco, was a recent guest at the University of Texas Medical Branch, Galveston, where he spoke on "Renal Factors in Hypertension."

WASHINGTON

New State Health Director—Dr. Leland E. Powers, health officer of Tacoma, has been appointed director of the Washington State Department of Health. He succeeds Dr. Donald G. Evans, Seattle, who according to *Northwest Medicine*, will enter private practice.

Personal—Dr. Robert H. Welding, Ellensburg, has been named health officer of Kittitas County.—Dr. John W. Unis, Seattle, has been appointed medical supervisor for the department of social security. He succeeds Dr. John M. Flude, Olympia, who resigned to enter private practice in California.

WYOMING

State Medical Election—Dr Thomas J. Rich, Casper, was chosen president-elect of the Wyoming State Medical Society at the meeting of its house of delegates in Casper, June 6. Dr Paul E. Wheldon, Sheridan, was installed as president. Other officers are Drs George H. Phelps, vice president, Frederick L. Beck, treasurer, and Marshall C. Keith, secretary, all of Cheyenne.

GENERAL

Public Meeting on Enrichment of White Flour—A public meeting to consider the advisability of requiring all white flour distributed for human consumption to be enriched will be held on July 21 in the South Agriculture Building Auditorium, Washington, D. C. There is a federal standard for enriched flour which at present requires specific quantities of thiamine, niacin and iron. Beginning on October 1 the vitamin riboflavin will also be required. The need for a wide distribution of the vitamins and minerals contained in enriched flour was the basis for the provision of Food Distribution Order number 1 requiring enrichment of all bakery white pan bread. In order that all white bread, whether baked in the home, in an institution or in the commercial bakery, may contain these essential nutritive factors, it has been proposed to enrich all white flour distributed for human consumption. A proposed order has been drafted in accordance with recommendations received from the National Research Council. The effective date of the order, if issued, will be made not less than one hundred and twenty days after its date of publication, affording millers who have not enriched their flour an opportunity to obtain necessary equipment and materials. Likewise bakers who are enriching bread by other means will have an opportunity to consume their stocks of enrichment agents. Persons unable to attend the public meeting may address expressions of opinion to the Director of Food Distribution, War Food Administration, Washington, to be received not later than July 26.

Meeting of Board of Obstetrics and Gynecology—At the annual meeting of the American Board of Obstetrics and Gynecology in Pittsburgh, May 20-25, 108 candidates were certified. A number of changes in board regulations and requirements were put into effect. Examples are the allowance of a stipulated amount of credit toward special training requirements for men in service and assigned to general surgical positions, special training allowances on a preceptorship basis for men assigned to obstetric or gynecologic duties in military hospitals and working under the supervision of certified specialists or recognized obstetrician-gynecologists, as well as credit toward the "time in practice" requirement of the board to be allowed for time in military service. The board will no longer require a general rotating internship but will now accept a one year intern service. Such services must be in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association. The privilege of reopening applications by candidates who have been declared ineligible has been extended to two years from the date of filing the applications instead of one year. The board has ruled temporarily to excuse men in military service from the submission of case records at the stipulated examination times, thereby permitting them to proceed without further delay with the board examinations. This does not obligate the board, however, to waive the case record requirement for such candidates. Plans have been made to provide similarly for service men on their eventual discharge from the armed forces and to permit the greater use of operations done while in residency or in civilian practice before the war. Applications and bulletins of detailed information regarding the board requirements will be sent on request to the secretary, Dr Paul Titus, 1015 Highland Building, Pittsburgh.

Committee of Physicians for the Improvement of Medical Care, Inc., Issues Statement—On July 6 the Committee of Physicians for the Improvement of Medical Care, Inc., which is apparently the continuing body of the so-called Committee of Four Hundred which was prominent around 1937, issued a statement which apparently is being circulated to those who signed its first communication. The committee now includes Drs Channing Frothingham, chairman, Milton C. Winternitz and Carl A. L. Binger, vice chairmen, Russell L. F. Cecil, honorary chairman, John P. Peters, secretary and treasurer, and Bertram M. Bernheim, Ernst P. Boas, Samuel Bradbury, Allan M. Butler, Hugh Cabot, Louis Casamajor, Thomas B. Cooley, Charles A. Flood, Francis T. H'Doubler, William J. Kerr, H. Clifford Loos, George M. Mackenzie, Harry S. Mackler, Thomas Guier Miller, George R. Minot, Robert B. Osgood, Henry B. Richardson, G. Canby Robinson,

David Seegal, Richard M. Smith, Borden S. Veeder and Mortimer Warren. In this statement the committee duplicates a letter in which it congratulates Senator Robert F. Wagner for presenting the Wagner-Murray-Dingell bill. The committee states that it will give the bill careful consideration and report results of its studies at an early date. On the subject of medical education the committee states that it is hesitant to criticize but feels nevertheless that several features of the program established by the armed forces are open to criticism. The committee feels that control of the educational system should not be left to the military authorities but that it is preferable to establish "at once a comprehensive authority to assume direction of medical education, with separate bodies responsible for the major scientific and technical branches." On the subject of medical manpower the committee accepts in toto the recent report from the Office of War Information and says "One centralized federal body should be given responsibility for the control of medical manpower." It argues that this should be the United States Public Health Service and that this service should provide not only doctors but also nurses and other personnel and all the facilities of modern medicine. It states that use should be made of Negro physicians and qualified refugee physicians in meeting shortages in various areas. In order to prevent competition with medical practice, it is proposed that the fees collected by these physicians from those able to pay should be turned over to a federal agency for expansion of local health service under the direction of the United States Public Health Service. The report states that this will require at most four thousand physicians. In discussing the National Physicians Committee for the Extension of Medical Service, the committee indicates that it is confused as to the nature of the conduct of the National Physicians Committee and attacks the National Physicians Committee for its point of view regarding the private practice of medicine.

LATIN AMERICA

New Medical Journals—*Obstetricia y Ginecologia Latino Americanas*, a bimonthly journal, made its first appearance with the February 28 issue. Dr Manuel Luis Perez is the editor. The headquarters are at Calle J. E. Uribe 157, Buenos Aires.—The first issue of *Boletín Médico Mexicano* appeared in January. Dr L. B. Robinson is the director and J. P. Martinez the editor. The headquarters are at Calle de Bolívar Num 23, desp 116, D. F., Mexico.

Roving Doctors Care for Rubber Tappers—Rubber tappers in remote malaria infested jungles of Central America are being cared for by a new type of roving doctor, the practitioner. The practitioner usually is a young medical student with sufficient practical knowledge to treat the rubber tappers for malaria, wounds and insect bites and similar ailments common to forest workers. One practitioner working in the departments of Peten and Quiché saw 99 tappers and their families in a month's travel of 300 miles by boat and mule. In this group 26 men were found with malaria. Practitioners are being assigned to this work in various parts of Central America where the Institute of Inter-American Affairs is cooperating with local authorities in the organization of health services for workers.

Health Projects Surmount Wartime Material Shortages—Wartime shortages of steel, concrete and other construction materials have not halted the inter-American health and sanitation program in Central America. Scores of health facilities are being pushed to completion, including health centers, clinics, hospitals, water supply and sewerage systems, surface drainage installations for malaria control and other health projects. To meet the problem of diminishing supplies an announcement from the Institute of Inter-American Affairs states that the engineers have revived old techniques of building used a hundred years ago, discovered substitutes for concrete from local materials and used Indian craft. In an inter-American project for malaria control at San Miguel, Guatemalan inverts are used to meet the shortage of cement. The inverts are made in the same fashion in which Indians produced pottery before the arrival of the white man.

CORRECTION

Wetting Agent Formula—In the report of the Committee on Occupational Dermatoses on Recognition and Prevention of Industrial Dermatitis, which appeared in THE JOURNAL, formula 11 of a wetting agent should have read

FORMULA 11

Sulfonated olive oil
Light liquid petrolatum
Sulfonated neat's foot oil
Gelatin, 25 per cent aqueous solution

Medical Results in the Tunisian Campaign

The treatment of the British wounded in the Tunisian campaign seems to have been the most successful recorded in war. This result can partly be explained by the innovation of transport by air. Toward the end of the previous great war one British hospital in France had 1,300 severely wounded, of whom 113 died. In Tunis a similar hospital had 1,500 severely wounded, of whom only 5 died. Full statistics are not yet available, but we are assured that when they are they will amaze the world. There has been no tetanus and little gas gangrene, and sepsis has been largely controlled by sulfonamides. These results have been achieved in spite of great transport difficulties. The wounded had to be moved hundreds of miles, sometimes by motor ambulance, sometimes by hospital train. Once we gained air superiority it was possible to send them by hospital ship. But the most valuable means of transport were troop carrier aircraft fitted to take 18 stretcher cases, as well as air crew, doctor and nurses. More than 15,000 wounded were evacuated by air, usually to Algiers or Oran, sometimes to Gibraltar, occasionally even to America or England. In April alone 7,000 were thus transported. Aircraft also carried medical supplies in the opposite direction. One flew plasma to the Eighth Army in Tripoli. The most remarkable achievement was to fly the whole of a small general hospital to American troops isolated in desert country. The job took eighty loads, but it was done in one day.

The lives of many wounded in Tunisia were saved by blood transfusion and many more by major operations performed closer to the firing line than ever before. Our new field surgical units, staffed by young surgeons, have done miracles under fire. The air-borne surgical team proved worthy of the parachutists whom it served and with whom it dropped. One surgeon broke his leg above the knee in landing. He concealed the injury for three weeks during which he performed a number of major operations, giving himself a local anesthetic between operations. Another had a severe wound for thirty-one hours.

The general health of the First Army was no less remarkable than its recovery from wounds. Probably no force on active service has ever been healthier. The much disliked inoculations produced complete absence of tetanus and almost complete absence of typhoid. There were hardly any typhus cases, though there was much typhus in the country and there was a severe epidemic during the previous winter. The malaria season began last month but plans to control the disease were begun in January. All the troops now take antimalaria pills, which they dislike very much.

An Indian Army Medical Corps to Be Formed

A recent example of the endeavor of the British government to promote the advancement of the various peoples of the empire is in the medical sphere. The immediate formation of an Indian army medical corps, to be organized on lines similar to those of the medical corps of the British army, is announced. It will take the place of the existing Indian Medical Service which is now rather more European than Indian. This action follows the visit to India of the Medical Personnel Mission which was headed by Mr. H. S. Souttar, chairman of the council of the British Medical Association and included the director general of the army medical service and a former director general of the Indian medical service. The mission was sent at the request of the government of India. The two

sources of supply of doctors in India are the graduates (about 12,000) and the licentiates (about 35,000). The graduates have passed through a full medical curriculum and have acquired a qualification registrable in Britain. Many of them have attained distinction and are capable of specialized work of high order. For the licentiates we have no exact parallel here. They vary much in primary education and professional attainments. But their training has been much improved in recent years and many of them are skilled and compete successfully in civil practice with the graduates. The mission visited Cairo on their way to India and made special inquiries about the work of the licentiates in the war and found that their commanding officers considered them capable of full medical responsibility. They have already been employed in the Indian army but with lower rank and less pay than the graduates.

The mission proposed—and the proposal has been accepted by the government—that all candidates for a commission in the new medical corps, whether graduates or licentiates, shall undergo at least a three-months preliminary course of training in subjects important for military service, such as anesthesia, blood transfusion, war wounds, nutrition, tropical diseases and hygiene. They will be under close observation during this period, and on the report given by the commandant will depend the bestowal of a commission. The most noteworthy reform is that every doctor qualified to practice in India will have the opportunity to rise in the corps to any position which his abilities justify.

The absence of an effective nursing service from the Indian army impressed the mission. There are only 300 registered male nurses in the whole of India. The bulk of the nursing is performed by sepoys who have received only a brief military training. The attempt will be made to attract to the army a superior class of men, who will be trained in nursing and first aid.

A tribute should be paid to the highly efficient Indian medical service, which is now to be superseded. It began as a purely British service, but with the progress of medical education in India it became more and more Indian. At the outbreak of the war it numbered 780, of whom 60 per cent were European and 40 per cent Indian. The number is now 2,838, of whom only 20 per cent are European. Thus the wartime increase has been almost entirely Indian. It was from the Indian medical service that the most important British advances in tropical medicine came. The most important example was the discovery of the malarial parasite by Ross.

Attacks on Hospital Ships

The recent torpedoing and sinking of the Australian hospital ship *Centaur* by the Japanese has recalled the frequency with which this outrage has been perpetrated by the Germans and Italians. In the House of Commons Sir William Davison, First Lord of the Admiralty, gave a list of twenty-six Axis attacks on hospital ships, beginning with the *Atlantis*, which was bombed four times off Norway from May 1 to May 11, 1940 but escaped damage. Many were severely damaged and three were sunk. All forms of attack—bombing, dive bombing, machine gunning, shelling and torpedoing—were suffered with much loss of life to patients, medical staff and nurses. All the ships were properly marked in accordance with the Geneva Convention but this did not save them. It is curious that the last attack on a British hospital ship according to the official list was on May 10, 1942, when the *Ramb IV* was bombed and sunk near Alexandria.

Norwegian ships have also suffered. From the Norwegian government information office in London H. K. Lemkuhl has written to the *Times* describing the sinking of Norwegian hospital ships. On April 24, 1940, the hospital ship *Bratt II* was bombed by German dive bombers outside Långsund. One doctor, two nurses and three ambulance men were killed. Thus

ship was clearly marked with red crosses. The survivors were also machine gunned from the air after they had succeeded in landing on an island. On April 20, 1940 the hospital ship *Queen Maud*, also clearly marked with red crosses, was bombed at Girtangen, north of Narvik. There were 22 casualties. On June 9, 1940 the hospital ship *Isadna*, white painted and clearly marked with red crosses, was bombed and sunk outside Tromsø during the evacuation.

Wartime Changes at Oxford

The opening of term is marked by various professorial changes. Sir Farquhar Buzzard retires from the regius professorship of medicine and is succeeded by Prof. Arthur Ellis. Prof. J. A. Ryle becomes the first professor of a new chair—social medicine.

AUSTRALIA

(From Our Regular Correspondent)

April 13, 1943

Opposition to a Salaried Medical Service

Unified opposition to change in the present system of medical practice was expressed at a recent convention in New South Wales, which adopted the motion that "a whole time salaried service for a nationwide medical service is not in the interests of the community." The convention, which consisted of representatives of medical organizations in the state of New South Wales called together by the council of the New South Wales branch of the British Medical Association, was held in Sydney on February 4 and 5. In his inaugural address Sir Charles Blackburn said that there was a certain amount of resentment that the discussion would center to a large extent around a scheme submitted by the National Health and Medical Research Council, and there was a strong feeling that the government had slighted the medical profession by not coming direct to it for its advice on a matter about which it was most competent to speak.

The convention was of the opinion that the optimum efficiency of medical service to the people of Australia could be provided under the existing structure of consultant, general practitioner and hospital services together with the adoption of certain measures which included the extension of group practice initiated by members of the profession themselves. The principle of free choice of doctor and patient and the maintenance of the personal relationship between them was upheld. A motion was carried to the effect that complete disciplinary control of members accepting service in any scheme which might be initiated should be exercised only by members of the British Medical Association. The convention was opposed to any change being made in the status of the medical profession and conditions of medical practice during the currency of the war and for a period of one year after its termination and resolved that the federal council of the British Medical Association be instructed to oppose it by all possible means.

The Future of Medical Practice

That medical men are individualists is well proved by the evidence given by members of the profession before the Parliamentary Joint Committee on Social Security. While many of the witnesses have attempted to avoid committing themselves to any one policy for the reorganization of medical practice, a diversity of opinions has been expressed. Of some sixteen doctors who have given evidence before the committee, four were opposed to any radical change in the present system of medical practice, four preferred "fee for service" basis of payment or a scheme based on that functioning in New Zealand, four were in favor of a salaried medical service and two openly opposed it, three were wholly noncommittal and seven of the sixteen emphasized the importance of maintaining the personal relationship between doctor and patient.

Social Trends in Australian Medical Practice

Various schemes for a general medical service for Australia are now under consideration. These include (a) national health insurance as proposed under the National Insurance and Pensions Act of 1938, (b) the plan of the federal council of the British Medical Association in Australia for a medical service on a capitation fee basis, limited to a fixed income group of the population, (c) a scheme for medical, hospital and related benefits such as is in operation in New Zealand, where the "fee for service" system and the capitation system of payments are worked concurrently, (d) a salaried medical service such as that outlined by the National Health and Medical Research Council or by the Victorian Branch Council of the British Medical Association in Australia, or (e) evolution on the present basis of practice, without radical change or government control.

The inclusion of medical benefits under a national insurance scheme is not supported by any section of the community. The government is apparently in favor of a salaried medical service, but a large part of the medical profession is opposed to it. A considerable group of medical men consider that any radical change in the existing system of practice is unnecessary. The profession as a whole is of the opinion that no fundamental changes should be made before the end of the war.

Venereal Disease Control in the Army

Since the beginning of the war the incidence of venereal disease, except syphilis, has in this country remained surprisingly low. Measures adopted by the Australian army to combat the disease include lectures given by specialists to army medical officers and to combatant officers and noncommissioned officers, who in turn are expected to impart their knowledge to troops of their unit. Regimental medical officers are instructed to give frequent talks on the subject to their own particular units, and relevant articles written in nontechnical language for the education of the soldier are published from time to time in the army magazine *Salt*.

The army and civil authorities cooperate fully in tracing sources of infection and in bringing them under medical control. A monthly meeting, attended by commonwealth and state authorities, together with representatives of the services, including the United States Army, is held for the purpose of discussing the latest methods of prophylaxis and treatment and the means for coordinating efforts between the services.

Schools for the training of medical personnel in the prophylaxis of venereal disease are held at a special army hospital, and from these schools the staffs for various prophylactic depots are selected. The prophylactic depots, which have been established in large cities, in all standing camps and in numerous country towns where there are concentrations of troops in the vicinity, are built to standard design, efficiently equipped and open day and night. No names or regimental numbers are recorded, but prophylactic measures are withheld from men showing signs of venereal disease, which are reported to a medical officer. Condoms and "blue light" outfits containing a silver proteinate and mild mercurous chloride ointment are issued free on the application of troops proceeding on leave. An adaptation of a talking film produced by the Medical Corps of the United States Army is being exhibited to all services.

Special medical inspection is made of all troops on their entering camp, at various times during training, and before they go on draft. No diagnosis is attempted or treatment given in the field, but suspected cases are evacuated immediately to a special army hospital.

Army personnel suffering from syphilis were originally discharged as medically unfit and were reported to the director of social hygiene, who instructed them to report to a consultant physician or to the board of health. Many of these men are listed after completing their course of treatment. By a

recent arrangement soldiers infected with syphilis are treated at special hospitals until noninfective and then are drafted to an employment company for duty while continuing their weekly injections

Control of Contraceptives

During the past few years the general public has been increasingly menaced by "quack" commercial concerns, which have been capitalizing on the emphasis placed on venereal disease in wartime. Many have been sending literature relating to articles used for contraceptive purposes indiscriminately through the post or delivering it from house to house as part of advertising campaigns, and a large group of individuals have established themselves profitably as "consultants" on matters relating to birth control and other sex matters. In Victoria a few years ago an act was passed giving very stringent control over advertising and display, but in the other states no such control existed. Recently, however, the commonwealth government under national security regulations made it illegal to display, advertise or promote the sale of any article as a medicine, instrument or appliance for the alleviation of venereal disease or the prevention of contraception.

BRAZIL

(From Our Regular Correspondent)

June 14 1943

A New Antihemorrhagic Agent

In its issue of May 31, 1941 page 2521, THE JOURNAL published the conclusions of Drs. Eduardo Vaz and Mario Pereira of the Instituto Pinheiros, São Paulo, Brazil, in their studies on the action of snake venom as an antihemorrhagic agent (bothropase). Recently Dr. Alberto Barbosa Hargreaves of the University of Rio de Janeiro has studied the jararaca venom (Bothrops jararaca) so as to obtain thromboplastic material in dosage of prothrombin. The solution of crystallized snake venom in a concentration of 1:15,000 is added to an equal amount of a solution of calcium chloride in a concentration of 1:11 per cent. From this mixture 0.2 cc. is added to 0.1 cc. of plasma. The time between the addition to plasma and the beginning of the formation of net of the fibrin is noted by a chronometer. The operation is repeated with diluted plasma until the concentration of 20 per cent, and curves are made after the dilution. By this method curves are obtained like those with the use of rabbit's brain thromboplastin. The author concluded that the action of the mixture snake venom plus calcium plus plasma is equal to the thrombokinase plus calcium plus prothrombin. According to comparison with the results obtained with Russell viper venom the snake venom demonstrated a powerful action. The differences noted in the highest dilution are probably due to the minor power of the viper venom in relation to the jararaca venom.

Neuromas of the Appendix and Chronic Appendicitis

Dr. João Montenegro of the Instituto Adolfo Lutz of São Paulo made recently a general survey of the so-called neuromas of the appendix mucosa as the cause of appendalgia. He reviewed the works of Masson, Maresch and Rossle on the matter and accepts the hypothesis that the nervous hyperplasia of the mucosa possibly results from inflammation stimuli but these structures are not amputation neuromas.

Regarding the clinical meaning of such structures, Montenegro emphasizes the difficulty in establishing the facts. The false conclusions come perhaps not so much from a too short follow-up postoperative period as from unreliable information furnished by the patients whether consciously or, more commonly, subconsciously. He thinks that the high percentages of cure formerly reported after operations for chronic appendicitis were largely exaggerated and, on such a false basis, wrong

conclusions were drawn regarding the value of the minor pathologic findings of the appendix. He says that one may admit that very exceptionally these so-called neuromas of the mucosa may be so numerous and bulky as to cause stenosis of the appendix lumen and give rise to disease curable by appendectomy, but that is nothing compared to the enormous number of patients operated on for chronic appendicitis in whose appendix there were neuromas with or without active inflammation, in these cases the cure was not obtained because of a chronic typhlocolitis.

Montenegro reports 45 cases in which he operated with the diagnosis of chronic appendicitis. The histologic sections of the appendix were stained by the trichromic method of Masson and some by silver impregnation. In 9 cases the so-called neuromas were found. Only 1 of these patients was cured, but in his appendix there was also a focus infiltrated with leukocytes situated in the muscular coats and extending down to the submucosa, occupying an area of about 1 millimeter. Five of the patients were not relieved of their symptoms and they have now a chronic nonspecific colitis which they probably had concomitantly with the appendicitis.

Since the symptoms of chronic appendicitis are as a rule equal to those of chronic typhlitis and since these two disorders often coexist, it is impossible in such cases to assign the roles played by the appendix lesions.

Chagas Disease

Chagas disease is well known as a peculiar tropical disease (trypanosomiasis) described by a Brazilian scientist Dr. Carlos Chagas of the Instituto Oswaldo Cruz, Manguinhos, Rio de Janeiro. Until a few years ago it was believed that this disease was transmitted only by wild insects. Although Chagas had verified infestation of cats and dogs by the parasite of the American trypanosomiasis it has not been proved until now that those animals can transmit the disease to human beings. Recently, as a result of researches carried out in a country village of the state of Rio Grande do Sul, Dr. D. J. Clausell demonstrated that the dog is the vector of the parasite and responsible for Chagas disease in a district where no wild insects are to be found.

Marriages

ROCKWOOD WILDE BULLARD JR., St. Clair, Mich., to Miss Maryetta Moylan Fitts of Drewrys Bluff, Va., in Chicago April 24.

ALEXANDER J. STEIGMAN, Philadelphia, to Miss Katherine Colvin of Arlington Heights, Ill., in Salisbury, England, June 26.

SAMUEL JOHNSON FAIRSTEIN, to Miss Alice M. Atwell, both of Mount Vernon, N. Y., at Norfolk, Va., June 28.

JAMES STUART KNIFE, San Jose, Calif., to Miss Kathleen Mary Newman of Clear Lake, Iowa, June 8.

JAMES N. PROFFITT, Nashville, Tenn., to Miss Ruth Elizabeth Goddard of Alcoa, in Maryville, in June.

WILLIAM JEROME BRUCKNER, Brooklyn, to Miss Alice Jeanne Lamb at Wellington, New Zealand, April 6.

JULIAN CARR LENTZ JR., Durham, N. C., to Miss Mary Nell Lee of Maryville, Tenn., in Athens, Tenn., June 19.

HUGH CATHCART CHARLESTON S. C., to Miss Marguerite McDonnell in Washington, D. C., June 19.

FREDERICK GEORGE KRONCKE, Roanoke Rapids, N. C., to Miss Jeannette Valentine of New York, June 4.

HENRY L. WATSON, Tampa, Fla., to Miss Tallulah Josephine Newman of Woodruff, S. C., May 26.

RUSSELL PEYTON HARRIS JR., Newell, N. C., to Miss Bernice Carolyn Carter of Asheville, June 12.

DONALD WALTERS, Charlottesville, Va., to Miss Babette R. Rothschild in Philadelphia, June 3.

WILLIAM L. BLANCH JR., to Miss Lucile Stevens, both of Fayetteville, Ark., June 16.

Deaths

Clifford Black Walker ☉ Los Angeles, Johns Hopkins University School of Medicine, Baltimore, 1911, clinical professor of surgery (ophthalmology) at the University of Southern California School of Medicine, formerly professor of clinical ophthalmology at the College of Medical Evangelists, at one time assistant in ophthalmology at the Harvard Medical School, Boston, served as a member of the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, Association for Research in Ophthalmology, Inc., Western Ophthalmological Society and the Pacific Coast Oto-Ophthalmological Society, past president of the Los Angeles Society of Ophthalmology and Otolaryngology, served on the staff of the California Hospital, Eye and Ear Hospital, Good Hope Clinic, Los Angeles County Hospital and the Hospital of the Good Samaritan, formerly on the staff of the Peter Bent Brigham Hospital, Boston, in 1914 received the first Knapp Medal from the Section on Ophthalmology of the American Medical Association for his paper on "Topical diagnosis of the Hemorrhagic Pupillary Reaction and the Willbrand Hemianopic Prism Phenomenon, with a New Method of Performing the Latter", aged 58, died, July 3.

Murray Snell Danforth ☉ Providence, R I, Johns Hopkins University School of Medicine, Baltimore, 1905, specialist certified by the American Board of Orthopaedic Surgery, Inc., recently elected president and formerly vice president of the Rhode Island Medical Society, past president of the Providence Medical Society, member of the American Orthopaedic Association, American Academy of Orthopaedic Surgeons and the New England Surgical Society, chairman of the Rhode Island Committee for Crippled Children, fellow of the American College of Surgeons, served as a major in the medical corps of the U S Army during World War I, chief, fracture service and consultant in the orthopedic service, x-ray and physical therapy department, Rhode Island Hospital, consulting orthopedic surgeon to the Butler Hospital and Charles V Chapin Hospital, Providence, South County Hospital, Wakefield and the Westerly (R I) Hospital, aged 64, died, June 5, of cerebral hemorrhage.

Harold Ward Dana ☉ Brookline, Mass., Harvard Medical School, Boston, 1905, assistant in bacteriology at his alma mater from 1911 to 1913, formerly instructor in clinical medicine, assistant professor of theory and practice of medicine, associate professor of medicine and clinical professor of medicine at the Tufts College Medical School, Boston, specialist certified by the American Board of Internal Medicine, served as a major in the medical corps of the U S Army during World War I, fellow of the American College of Physicians, member of the American Association for the Advancement of Science and the American Heart Association, at one time on the staff of the Boston City Hospital, aged 65, died, May 8, of pneumonia.

Stella May Gardner, Chicago, Northwestern University Woman's Medical School, Chicago, 1899, member of the Illinois State Medical Society and the American Society of Clinical Pathologists, specialist certified by the American Board of Pathology, Inc., inspector of schools from 1899 to 1905 and member of the board for physical examination of teachers in public schools from 1905 to 1920, formerly professor of laboratory diagnosis and assistant professor of microscopic and clinical diagnosis at the University of Illinois College of Medicine, part owner of the Lincoln-Gardner Laboratory, aged 75, died, May 5, in the West Suburban Hospital, Oak Park, Ill., of myocarditis and arteriosclerosis.

Andrew Sloan ☉ Utica, N Y, Columbia University College of Physicians and Surgeons, New York, 1902, member of the House of Delegates of the American Medical Association at the 1935 special session, fellow of the American College of Physicians, a charter member and for many years president of the Utica Academy of Medicine, formerly first vice president of the Medical Society of the State of New York, chairman of the medical advisory board, Utica Visiting Nurses and Child Health Association, member of the consulting service, Marcy (Pa.) State Hospital, the Children's Hospital Home and St Luke's Home and Hospital, where he died, April 21, of cardiovascular disease, aged 63.

Chancey Adams ☉ Concord, N H, Medical School of Maine, Portland, 1891, formerly a druggist, member of the state board of health from 1903 to 1906, for many years county medical referee, past president of the Concord medical division

of the bureau of pensions, formerly city physician and physician of the state prison, member of the advisory board during World War I, fellow of the American College of Surgeons, surgeon emeritus on the staff of the Margaret Pillsbury Hospital and consulting physician for the New Hampshire State Hospital, aged 82, died, May 11, of coronary sclerosis.

Frank Roscoe Makinson ☉ Oakland, Calif., Oakland College of Medicine and Surgery, 1913, member of the House of Delegates of the American Medical Association in 1940, fellow of the American College of Surgeons, past president of the Alameda County Medical Society, councilor of the Seventh District of the California Medical Association, served as president of the Public Health League of California, on the staffs of the Peralta, Samuel Merritt and Providence hospitals, aged 57, died, April 18, in the University of California Hospital, San Francisco, of lymphosarcoma.

Lee L. Armistead, Campbell, Ala. (licensed in Alabama in 1892), aged 78, died suddenly, May 7, of coronary thrombosis and arteriosclerosis.

Engelbert Charles Bender ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1902, aged 63, on the staff of the Misericordia Hospital, where he died, May 3, of heart disease.

Frederick Otto Bowe ☉ Chicago, Northwestern University Medical School, Chicago, 1903, associate in obstetrics at his alma mater, served as a member of exemption board number 63 during World War I, past president of the staff, and chairman of the obstetric and gynecologic section of the Illinois Masonic Hospital, on the staffs of the John B. Murphy and Evangelical Deaconess hospitals, aged 64, died, May 20, of coronary thrombosis and arteriosclerosis.

Bernard Laurence Campbell, Milwaukee, Chicago Medical College, 1884, past president of the Waukesha County Medical Society, examiner for the draft board during World War I, aged 89, died, April 26, of probable carcinoma of the stomach.

Robert Cathcart Jr., Lakewood, Ohio, University of Edinburgh Faculty of Medicine, Scotland, 1938, member of the Ohio State Medical Association, diplomate of the National Board of Medical Examiners, medical director, civilian defense in the village of Fairview, aged 31, died, May 20, in Dallas, Texas, of military tuberculosis.

Ulysses Simpson Cordell, Macomb, Okla., Chattanooga (Tenn.) Medical College, 1895, member of the Oklahoma State Medical Association, aged 74, died, May 28, of myocarditis.

John De Rosa ☉ Paterson, N J, Licentiate in Medicine, Surgery and Midwifery of the Apothecaries' Society of London, England, 1927, school physician, aged 43, on the staff of the Paterson General Hospital, where he died, April 22, of Hodgkin's disease.

William Roy Dillingham ☉ Salina, Kan., University Medical College of Kansas City, Mo., 1908, served as a captain in the medical corps of the U S Army during World War I, on the staffs of St John's and Asbury Protestant hospitals, aged 59, died, May 6, of hypertensive heart disease.

John A. Eichling, Gore, Okla., Barnes Medical College, St. Louis, 1898, aged 72, died, April 17, of heart disease.

Frank Barnett Farnsworth ☉ Janesville, Wis., Northwestern University Medical School, Chicago, 1898, one of the founders of the Munn-Farnsworth Clinic, aged 79, on the staff of the Mercy Hospital, where he died, May 5, of heart disease.

August Anton F. Gossow ☉ St. Charles, Mo., St. Louis College of Pharmacy, 1886, Beaumont Hospital Medical College, St. Louis, 1892, past president of the St. Charles County Medical Society, served during World War I, lieutenant colonel in the medical reserve corps of the U S Army, not on active duty, city physician, served two terms as coroner of St. Charles County, aged 74, died, April 27, in the Veterans Administration Facility, Jefferson Barracks.

William Henry Graham, Springfield, Ohio, Eclectic Medical Institute, Cincinnati, 1901, member of the Ohio State Medical Association, aged 67, died, April 13, of cerebral hemorrhage.

Benjamin H. Gray ☉ Richmond, Va., University College of Medicine, Richmond, 1903, specialist certified by the American Board of Obstetrics and Gynecology, Inc., professor of clinical obstetrics at the Medical College of Virginia, member of the South Atlantic Association of Obstetricians and Gynecologists, fellow of the American College of Surgeons, president and on the staff of the Stuart Circle Hospital, on the staff of the Memorial Hospital, aged 64, died, April 15.

Edgar M. Hughes, Truscott, Texas (licensed in Texas under the Act of 1907), aged 74, died, April 15, in a hospital at Wichita Falls of cerebral arteriosclerosis.

Frank Louville Juddins, Lynn Mass Medical School of Maine, Portland 1879, member of the Massachusetts Medical Society, a founder, first president and for many years chief surgeon at the Union Hospital, aged 90 died April 20 as the result of injuries received in an automobile accident in March 1942

Mark Keller, McKeesport, Pa University of Pittsburgh School of Medicine, 1924, aged 43, died, April 28, of heart disease.

Clifford Paul Krohn, Morrow Ohio Eclectic Medical Institute, Cincinnati, 1904, served during World War I, aged 70, died, April 13, in Cortez, Fla, of heart disease

Theophile Laurin, Lowell, Mass., Baltimore University School of Medicine, 1895, University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1899 member of the Massachusetts Medical Society, aged 72, died, April 10, of heart disease.

Winbon Joseph Long, Townsend Ga., University of Georgia Medical Department, Augusta, 1899, aged 68, died in April of cardiovascular disease

Franklin Fulforth Massey, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia 1903, served as a captain with the American Expeditionary Forces during World War I and held a reserve officers commission until 1926, past president of the board of health of Womelsdorf, Pa., at one time on the staff of the Homeopathic Hospital, Reading, Pa., aged 61, died April 9 in the Hahnemann Hospital of congestive heart disease, cirrhosis of the liver and uremia

Charles Lee McCann, Dallas Texas College of Physicians and Surgeons Baltimore 1887, aged 83 died, April 16, of arteriosclerotic heart disease and bronchopneumonia

Alvah John McCarter, Chicago Bennett Medical College, Chicago, 1914 member of the Illinois State Medical Society, served on the staff of the American Hospital, aged 63, died, March 31, in Menominee, Mich of chronic myocarditis

Harold James McDonald of Buffalo, St Louis University School of Medicine, 1910 diagnostician for the city health department for many years, formerly city physician, served on the staffs of the Children's Hospital, Edward J Meyer Memorial Hospital, St Mary's Infant Asylum and Maternity Hospital and the Emergency Hospital of the Sisters of Charity, where he died, April 25, of acute congestive heart disease aged 54

Wilson Davis McNary of Milwaukie, Ore., Vanderbilt University School of Medicine Nashville, Tenn, 1894, for many years superintendent of the Eastern Oregon State Hospital, Pendleton, aged 69, died, April 9, in the Good Samaritan Hospital, Portland

Daniel Arnel Metzgar, Braddock Pa., Western Pennsylvania Medical College, Pittsburgh, 1896 member of the Medical Society of the State of Pennsylvania, surgeon in chief at the Braddock General Hospital aged 71, died, April 17, at his home in Edgewood of coronary occlusion

John Robert Monihan, Cleveland University of Buffalo School of Medicine, 1912 served as a captain in the medical corps of the U S Army during World War I member of the staffs of St. Luke's, St. John's and Lutheran hospitals, aged 52 died April 21

Arthur Rembrandt Moore of Portsmouth Ohio, Bellevue Hospital Medical College New York, 1892 during World War I served overseas as a captain in the medical corps of the U S Army city physician from 1935 to 1942, served on the staffs of the Mercy and Portsmouth General hospitals, aged 72 died, April 7, of angina pectoris

Edwin Jarrett Nevill, Houston Texas University of Nashville (Tenn) Medical Department, 1874, aged 93 died May 16, in the Heights Hospital of heart disease.

William James O'Malley, Miami, Fla Maryland Medical College Baltimore, 1912, served during World War I, aged 58, died April 11

Robert Linn Osborn, Clarksburg, W Va University College of Medicine, Richmond 1908 member of the West Virginia State Medical Association, veteran of the Spanish-American War and World War I, formerly a colonel in the West Virginia National Guard member and formerly chairman of the Harrison County Selective Service Board number 1, city health officer, aged 60 died April 13

Thomas Joseph O Toole of Eagle Grove Iowa Omaha Medical College, 1896 past president of the Wright County Medical Society president of the Security Savings Bank part owner of the O Toole Christensen Hospital aged 72 died, April 14, of carcinoma of the throat.

Samuel M Pittman, Galesburg Ill., Rush Medical College Chicago 1888, aged 80, died, April 16, in Galva of cerebral hemorrhage

Max Lawrence Polowe, New York University and Bellevue Hospital Medical College, New York, 1903, aged 63, died, April 14

Saul Max Rubinow of Newark, N J., University of Moscow Faculty of Medicine Russia, 1897, served as a captain in the medical corps of the U S Army during World War I, examining physician for Selective Service Board number 23, served on the staffs of the American Legion Memorial, Presbyterian St James and Beth Israel hospitals vice president of North American Building and Loan Association and a director of Barton Savings and Loan Association, aged 70, died, April 13, of coronary thrombosis and arteriosclerosis

Matthew Maurice Ryan, Philadelphia, N Y The Hahnemann Medical College and Hospital Chicago, 1894, aged 75, died April 23, of myocardial degeneration

Campbell Sansing, Blossom Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1895, formerly associated with the U S Veterans Bureau, aged 70, died, April 3, of a self-inflicted gunshot wound

Henry Timrod Schiffler of Orangeburg S C Medical College of the State of South Carolina Charleston 1912 served overseas during World War I, aged 55 on the staff of the Tri-County Hospital, where he died, April 18 of chronic nephritis

Guy Graham Shaw Kaufman, Texas, College of Physicians and Surgeons Little Rock, 1909, member of the State Medical Association of Texas health officer of Kaufman, formerly health officer of Kaufman County, aged 57, died recently in a Dallas hospital

Arthur Burton Shimer of Atlantic City, N J Medico-Chirurgical College of Philadelphia, 1896, also a pharmacist, for many years on the staff of the Atlantic City Hospital, aged 74, died, April 23 of coronary thrombosis

Jacob Daniel Singer, Brighton Mich Western Pennsylvania Medical College Pittsburgh 1896 for many years physician for the Detroit Recreation Camp near Brighton member of the Volunteer Medical Corps during World War I, aged 84 died, March 15

George C Stemen, Denver Fort Wayne (Ind) College of Medicine 1886, formerly on the staffs of the old Denver General Hospital the Mercy and St. Joseph's hospitals at one time a member of the state board of health formerly secretary of the Denver branch of the medical division of the bureau of pensions, aged 78, died, April 10, of carcinoma of the prostate

James Walter Stiles Jr, New York University and Bellevue Hospital Medical College, New York 1902, aged 63, died, April 13 of carcinoma of the prostate

Michael Sullivan, Alhambra Calif College of Physicians and Surgeons Keokuk Iowa, 1878 at one time a pension medical examiner, served three terms as mayor of Adrian, Minn, and postmaster for four years aged 91, died, April 17, in Glendale of chronic myocarditis and arteriosclerosis

James Wallace Summers, Murfreesboro Tenn (licensed in Tennessee in 1896), aged 74, died, April 17, in the Rutherford Hospital of heart disease

William Thomas Thornton of Missoula Mont American Medical Missionary College, Battle Creek Mich and Chicago 1903 part owner of a hospital bearing his name, aged 65, died, April 28 of multiple myeloma

Leopold Wedeles, Chicago Deutsche Universität Medizinische Fakultät Prague Austria 1890 member of the Illinois State Medical Society served on the staff of St. Anthony de Padua Hospital aged 80, died March 18, of pulmonary embolism

George Frank Zerzan of Holbrook Kan Rush Medical College Chicago 1900 also a pharmacist served during World War I aged 64 died March 22 in St. John's Hospital Salina of arthritis and carcinoma of the pancreas

CORRECTION

Commander Lipshutz Not Killed in Action.—Information recently received from Capt. Lowell F Bushnell M R C U S Army and the Surgeon General's Office U S Navy indicates that Lieut. Comdr Joseph Lipshutz (MC), U S Navy died on Dec 17 1942 of a self-inflicted bullet wound THE JOURNAL, March 27 page 1107 reported the death of Lieutenant Commander Lipshutz under "Killed in Action"

"BROMIDISM"

To the Editor—In *THE JOURNAL*, June 19, page 496, Nielsen reports a case of bromidism from prostigmine bromide. The data given, however, are inadequate for such a conclusion. The patient could not have taken the drug for more than two hundred days, and the larger doses much less time. She had raised the dose until she took 240 mg per day. Had she taken 240 mg for two hundred days it would equal 48 Gm.

Since the bromine content of prostigmine bromide is approximately 26 per cent, 48 Gm would be equivalent to 15 Gm of sodium bromide or 18 Gm of potassium bromide. At death the patient's blood contained 225 mg of bromide per hundred cubic centimeters. If the total blood volume was 4,000 cc the total bromide in the blood would be equivalent to 9 Gm of sodium bromide. With this volume of blood a person should weigh about 52 Kg (115 pounds).

We may assume that the bromide in the blood and in the other fluids is dispersed in the same ratio as the chlorides. The total sodium chloride in the body is normally about 0.3 per cent of the body weight. For a person of 52 Kg the sodium chloride therefore should be about 156 Gm, of which about 32 Gm would be in the blood. If the blood contains the equivalent of 9 Gm of sodium bromide, therefore, under our assumption which is based on accepted data, the amount of bromide in the body of the case cited would be $32 \times 156 \div 9 = 563$ Gm, or $1 \div 44$ Gm of sodium bromide.

Since she consumed at most the equivalent of 15 Gm of sodium bromide in two hundred days, a large proportion of which would have been excreted, the likelihood of prostigmine bromide causing bromidism seems absurd. If the amount of bromide at death was 225 mg per hundred cubic centimeters of blood, it could not have come from the prostigmine bromide.

This seems to be another case of mistaken bromidism, of which there are already too many in the literature.

H. A. McGUIGAN, M.D., Chicago

REPORTS OF SUCCESSFUL ARTIFICIAL DONOR INSEMINATIONS

To the Editor—Artificial donor insemination is rightfully taking its place in the armamentarium of the physician who treats infertility. However, only when the husband has been shown to be absolutely sterile and all efforts to effect male fertility have failed should donor insemination be attempted. Reports of successful cases are appearing in the literature with greater frequency.

It is advisable, when reporting single isolated successful cases, that the physician (for the protection of the family concerned) deliberately omit certain of the details from his report. The following are examples of the type of facts which are best left unreported:

- 1 The date of the child's birth or the date of the successful impregnation
- 2 The locale or environs of the mother's residence
- 3 The age, sex and description of the baby
- 4 Exact details of the past history of the barren couple which may possibly be used to throw light on their identity

On the other hand, the complete details of the case history, with the solitary exception of the identity of the individuals concerned, should be available to interested reputable physicians or to recognized national medical committees.

ABNER I. WEISMAN, M.D., New York

"THE MENACE OF TYPHUS IN EUROPE"

To the Editor—Reference is made to the editorial appearing in *THE JOURNAL*, June 5, on "The Menace of Typhus in Europe." The editorial is based on Biraud's summary of the typhus situation in Europe and North Africa and his account of the typhus vaccines now in use. In both Biraud's account and in the editorial the statement is made that in the presence of typhus epidemics a live virus vaccine should be used on account of the short period required for the development of protection.

The theoretical considerations concerning inoculations with a living virus to produce an active immunity are championed by some and condemned by others. The living virus used in the live virus typhus vaccines is not that of epidemic (louse borne) but of endemic (flea borne or murine) typhus. There has been no attenuation of this murine virus since adequate dosage in animals will produce the typical disease. From this then it would seem that we would expect to see actual cases of endemic (murine) typhus developing in a certain proportion of vaccinated individuals if (1) slightly too strong a dosage of living virus was administered or (2) the susceptibility of part of or the whole group was greater than expected. Actually both of these circumstances have occurred in field vaccination, witness Biraud's account of the Chilean experience which was written off as improper dosage, and the statements in previous reports that the reactions in Europeans are too severe to warrant its use.

In addition, it should be noted that a fair percentage of those inoculated get no protection whatever. Attention should be given to the fact that this vaccine, depending on the presence of a living agent, may and probably does contain contaminating organisms which per se may be dangerous. As to the evidence of the value of the living vaccines, it should be noted that in the field work in North Africa with this vaccine some two or more million individuals were vaccinated. It should also be noted that no adequate controls were used, and no definite conclusions as to its value in the control of epidemics is warranted.

The opinion of opponents to the use of a living typhus vaccine may be summed up by stating that it is the consensus that any living typhus vaccine so far suggested is too dangerous and too uncertain to use. This is surely true for our troops.

A great deal of work has been done in recent years on killed typhus vaccines, and our troops destined for areas where typhus is present are vaccinated with such a vaccine. The vaccine manufactured in America will produce antibodies within two weeks sufficient to protect animals against the subsequent inoculation of the living agent of the disease. Killed vaccine also employs strains of epidemic (louse borne) typhus for protection against the epidemic (louse borne) type of the disease. The vaccine produces in man less reaction than typhoid vaccine. This vaccine can be and is now being produced in practically unlimited quantity. The evidence as to its value may be summed up by stating that it apparently gives good protection against death from subsequently acquired typhus and may so modify a later attack of the disease as to warrant the hope that lice cannot become infected by feeding on such a patient. Whether or not an epidemic of typhus can be controlled by any vaccine alone has not as yet been determined. The killed vaccine is sterile and therefore entirely free of danger of infection caused either by the presence of living typhus rickettsiae or by other organisms.

The control of epidemics of typhus lies in proper care and protection of cases and efficient delousing measures. Vaccine (killed) should be used as an adjunct.

THE EARLIEST DEMONSTRATION OF THE TUBERCLE BACILLUS IN THE UNITED STATES

Baldwin¹ writes that 'Edward L Trudeau was one of the earliest in America to appreciate the discovery made by Koch in 1882. He did not have the advantage of first hand contact with Koch as did Welch, Prudden and H P Loomis. Nevertheless he quickly acquired the technic of staining the bacillus from Prudden and Hodenpyl of the old laboratory of the College of Physicians and Surgeons in New York, as has been so graphically told in his autobiography. It is related that the late Surgeon General George M Sternberg was believed by his wife to be the first to stain the tubercle bacillus in America. However Dr T Mitchell Prudden visited Koch's laboratory in 1885 and brought back a thorough knowledge of the methods of the master.'

According to Winslow² the elder Flint brought the news of Koch's discovery to Welch who before many weeks were past succeeded in staining the bacillus by Koch's methods and also demonstrated it to his colleagues.

In the biography of her husband Mrs Sternberg³ states (p 87) that in 1881 he demonstrated and photographed the tubercle bacillus discovered by Professor Koch earlier in the

same year. I am informed on good authority that this was the first demonstration of the organism in America. A statement to the same effect is made on page 255. Obviously 1881 is a mistake, because Koch's announcement of his discovery was made on March 24, 1882.

Trudeau⁴ was immediately impressed with the full significance of Koch's discovery. He could not read German and was much pleased to receive for Christmas, apparently in 1882, an English translation of Koch's paper. In his account of learning to stain the bacillus he does not state clearly just when he worked in Prudden's laboratory, perhaps in 1883 or 1884. In 1885 he was staining the bacillus for diagnostic purposes. 'In the fall of 1885, as soon as I had equipped my little laboratory room I began to work. At first my knowledge was limited to the detection of tubercle bacilli in the secretions of patients' (p 201). At this time he began to cultivate the bacillus and he was undoubtedly the first one to do so in this country.

No account of the early study of the tubercle bacillus in this country is adequate without mention of the remarkable work of William T Belfield and Henry Gradle.⁵

When Koch's announcement was made, Belfield, then in Vienna, described the event in letters to a Chicago medical journal.⁶ Soon after his return he showed the tubercle bacillus at a meeting (October 1882) of the Chicago Pathological Society.⁷ This appears to be the first public demonstration of the bacillus in this country. Belfield remarked that on a recent occasion he had found the bacillus in 22 specimens of sputum. In February 1883 he gave the Cartwright Lecture⁸ in New York discussing in detail the discovery and the significance of the tubercle bacillus (pp 67-95) as well as the methods of staining it (p 129). He emphasized the diagnostic value of examining the sputum for the bacillus with clinical examples (p 90). In the summer of 1883 he stained the bacillus in the course of a necropsy in a case of pulmonary tuberculosis before medical students in the morgue of the Cook County Hospital, Chicago.⁹

In the same year 1883 Henry Gradle¹⁰ on his return from study abroad where he had worked with Koch also published a book on bacteria and disease in which the tubercle bacillus (pp 152-170) and its staining (p 162) are described in detail. On page 162 he wrote 'Apart from the fundamental scientific importance of Koch's work it has almost at once led to immediate practical results. Koch's own statement, that the bacilli are often present in the sputum of consumptives has been confirmed by a host of other observers so that the microscopic examination of the sputum possesses now a decided diagnostic value. It is necessary hence, to become acquainted with the mode of demonstrating the bacilli.'

The importance of microscopic examination in the diagnosis of consumption was emphasized also in a paper with Woltman early in 1883.¹¹

Belfield and Gradle were among the first in not the very first, to demonstrate adequately the tubercle bacillus in this country. It is noteworthy too that the book each wrote is one of the earliest books in the English language on the relations of micro-organisms to disease.

MEDICOLEGAL ABSTRACTS

Malpractice Angulation Following Complete Fracture of Humerus—The plaintiff, a boy aged 14 years at the time, suffered "a complete breaking" of the humerus of the left arm approximately at the junction of the lower and middle thirds of the humerus, the two broken ends of which overlapped. The child was taken to a hospital operated by the defendant partnership of physicians and was attended at times by different physicians, all of whom were orthopedists and were either employees of the partnership or copartners in the group. The fracture was reduced and traction applied. Some time later after the application of a plaster cast, the child was released from the hospital but returned at different times for observation and treatment. Considerable difficulty was experienced in effecting a union, and when union was effected angulation was present, the arm was $\frac{1}{2}$ inch shorter than before fracture and there was a large knob of bone at the point of union.

An action for malpractice was instituted against the copartnership and the physicians who attended the patient. The jury returned a verdict for the patient for \$8,500 and from a judgment on the verdict and from an order denying a motion made by the defendant physicians for judgment notwithstanding the verdict, the physicians appealed to the district court of appeal, second district, division 1, California.

In effect, the sole question for the determination of the appellate court was whether or not under the applicable law there was sufficient evidence in the record to support the verdict of the jury in favor of the patient. The degree of care and skill, said the court, required of physicians in treating patients is recapitulated in *Adams v. Boyce*, 37 Cal App (2d) 541, 99 P (2d) 1044, in part, as follows:

The law on the subject of the care and skill required of physicians in the treatment of patients is well settled and was epitomized in the case of *Hesler v. California Hospital Co*, 178 Cal 764, 767, 174 P 654, 655, where it was said that the law requires of the physician only "first, that he shall have the degree of learning and skill ordinarily possessed by physicians of good standing practicing in that locality, and second, that he shall exercise reasonable and ordinary care and diligence in treating the patient and in applying such learning and skill to the case. The law takes cognizance of human weakness and liability to err in the application of skill and learning and it requires only the exercise of reasonable and ordinary care and diligence to avoid error."

Concerning the obligations assumed by a physician when he undertakes to treat a patient, it is said in the same case at page 766 of 178 Cal at pages 655 of 175 P:

"A physician and surgeon, by taking charge of a case impliedly represents that he possesses, and the law places upon him the duty of possessing, that reasonable degree of learning and skill that is ordinarily possessed by physicians and surgeons in the locality where he practices, and which is ordinarily regarded by those conversant with the employment as necessary to qualify him to engage in the business of practicing medicine and surgery. Upon consenting to treat a patient, it becomes his duty to use reasonable care and diligence in the exercise of his skill and the application of his learning to accomplish the purpose for which he was employed. He is under the further obligation to use his best judgment in exercising his skill and applying his knowledge." *Pike v. Honsinger*, 155 N Y 201, 209, 49 N E 760, 762, 63 Am St Rep 655. "The difficulties and uncertainties in the practice of medicine and surgery are such that no practitioner can be required to guarantee results, and all the law demands is that he bring and apply to the case in hand that degree of skill, care, knowledge, and attention ordinarily possessed and exercised by practitioners of the medical profession under like circumstances." *Zotere v. Repp*, 187 Mich 319, 330, 153 N W 692, 695. "It is never enough to show that he has not treated his patient in that mode, nor used those measures, which in the opinion of others, even medical men, the case required, because such evidence tends to prove errors of judgment, for which the defendant is not responsible, as much as the want of reasonable care and skill, for which he may be responsible." *Leighton v. Sargent*, 27 N H 460, 474, 59 Am Dec 388.

What is or what is not, continued the court, proper practice on the part of the physician is uniformly a question for experts and can be established only by the testimony of such experts.

But it is not required that the evidence demonstrate conclusively and beyond possibility of a doubt that the defendants' negligence was the proximate cause of the plaintiff's injury, it is sufficient if there is substantial evidence which reasonably supports the judgment.

A medical expert witness called by the plaintiff was asked a hypothetical question concerning the treatment rendered by the defendant physicians predicated on (1) an alleged failure by the defendant physicians to have roentgenograms of the patient's arm taken frequently enough to keep them advised of the progress of the healing of the broken bone, (2) a failure properly to read or evaluate the roentgenograms themselves and then to take the necessary steps to correct the apparent progress of angulation of the union, (3) a possibility that too much traction had been applied, thereby keeping the broken ends of the bone apart so that they did not unite properly and straight, (4) a failure to maintain traction and casts on the arm for a sufficient length of time and (5) a failure to take proper measures to correct the angulation before the broken bone formed in a solid union impossible of being straightened except by operative means. In answer to the question and assuming the truth of the assumed facts, the witness stated that, in his opinion, the defendants did not exercise that degree of care and skill exercised and possessed by the average physician practicing in the locality and that "there was a degree of carelessness through the entire procedure," as stated in the hypothetical question. The testimony of this witness, in the court's opinion, was sufficient to support the verdict of the jury against the defendant physicians. Finally, said the court, when there is substantial evidence, as here, "from which the jury could infer that the course of treatment persisted in by defendant [sic] was not of that care, diligence and skill possessed and used by prudent, skillful and careful practitioners of medicine practicing in the same vicinity" a reviewing court will not set aside a determination of a jury that the defendant had been negligent.

The trial court instructed the jury that since the defendant physicians had held themselves out to be specialists and experts in the treatment of injuries such as that sustained by the plaintiff they must have and use the same degree of knowledge and skill ordinarily possessed and used by other specialists and experts of the same type in the particular locality and would be held to a standard of care and skill higher than that possessed and utilized by the ordinary practicing physician. The defendants contended that this instruction told the jury that there was required in this case a higher standard of care than generally in actions of this kind. But, answered the court, all defendants in this case were orthopedists and held themselves out as such. An orthopedist is a surgeon engaged in that branch of medicine which deals with the correction of deformities and chronic diseases of the joints and spine and, as stated in *Hopkins v. Heller*, 59 Cal App 447, 210 P 975:

One who holds himself out as a specialist in the treatment of a certain organ, injury or disease, is bound to bring to the aid of one so employing him, that degree of skill and knowledge which is ordinarily possessed by those who devote special study and attention to that particular organ, injury or disease, its diagnosis and its treatment, in the same general locality, having regard to the state of scientific knowledge at the time.

The instruction complained of, concluded the court, correctly sets forth the duty of the defendants in this case.

The judgment in favor of the patient was accordingly affirmed.—*Sansom v. Ross-Loos Medical Group*, 134 P (2d) 927 (Cal), 1943).

Society Proceedings

COMING MEETINGS

Oregon State Medical Society, Portland, Sept. 4-5, Dr. T. Robertson, St. Vincent's Hospital, Portland, Secretary.
Utah State Medical Association, Salt Lake City, Aug. 27-29, D. D. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent position only from them.

Titles marked with an asterisk (*) are abstracted below.

Prevalence of Pneumococci in Throats—The report by Smilie and his collaborators is a summary of the results of a study carried on from December to June of the years 1940 and 1941 of the prevalence of various types of pneumococci in the nasopharynxes of a group of occupants of one of the New York City municipal lodging houses. The purpose of the study was to determine the spread from person to person of the various types of pneumococci under conditions most favorable for transmission. The authors hoped to detect the invasion of a virulent strain of pneumococcus before the occurrence of actual disease and to follow the dispersion of this organism through the community. In the 111 men all the standard pneumococcus types except I and XXIII were encountered as well as many unusual types. Conditions were highly favorable for the

exchange of nasopharyngeal flora, and a multiplicity of types was found in many individuals, 1 man harboring seven different pneumococcus types. Many men were persistent carriers of the same type of pneumococcus. A type II pneumococcus invaded the community about February 24. Although everything seemed favorable for its dissemination through the group, only 4 men acquired the strain, and no lobar pneumonia or other serious consequences resulted. This is contrary to the experience in previous studies.

Gastritis and Peptic Ulcer—Of 40 patients with peptic ulcer Maher and her associates made satisfactory gastroscopic examinations of 28. Thirty-six of the patients were subjected to a partial gastrectomy and 4 were studied post mortem following injection of the stomach with solution of formaldehyde immediately after death. The criteria of gastritis were essentially those of Schindler. Atrophic gastritis of an arbitrary grade 1 to 4 was observed microscopically in 36 of the 40 patients. The gastritis did not vary essentially from that of 35 patients with gastric cancer except that hyperplasia was present in 16. The gastric mucosa appeared normal in 12 superficial gastritis was present in 10 and either hypertrophic gastritis or hypertrophic and superficial gastritis was present in 6 of the 28 patients on whom satisfactory gastroscopic examinations were made within one month of resection or necropsy. Microscopically, atrophic gastritis was present in the 12 cases that were normal at gastroscopy and in 13 of the remaining 16. This discrepancy may be explained partially by the presence of some atrophic gastritis in the so called normal stomach and by the masking of atrophic changes by superficial or hypertrophic gastritis. The fact that the gastritis associated with peptic ulcer is similar to that seen with gastric cancer suggests that the gastritis by itself may not be a specific precursor of either gastric cancer or peptic ulcer. The frequent microscopic evidence of atrophic gastritis in an apparently normal stomach indicates the necessity for further study of control groups of stomachs.

Penicillin Administered by Intrathecal Injection—The effect of penicillin on certain types of staphylococcal and pneumococcal meningitis which failed to respond to the sulfonamide drugs was studied by Rammelkamp and Keefer. Penicillin appeared in the blood stream for several hours after its intrathecal injection into patients with meningitis and its excretion was increased suggesting that penicillin is absorbed more rapidly when the meninges are inflamed. The results following injection into closed cavities were similar to those after intra-

theil injections in normal subjects in that absorption was slow and the total amount excreted in the urine was small. Significant amounts of penicillin remained in the spinal fluid for twenty-four hours. An intrathecal injection of 10,000 Florey units into a normal subject was followed by nausea, vomiting and headache. When 5,000 Florey units were injected, the only toxic symptom was a mild headache. There was a slight increase in the number of cells in the spinal fluid without an increase in the intrathecal pressure. In the presence of meningitis or cerebral abscess the injection of 3,000 to 10,000 Florey units was not attended by toxic symptoms. Necropsy on 2 subjects revealed penicillin in significant concentrations in the cisterna magna and the third ventricle, indicating that after lumbar injections the antibiotic agent will diffuse throughout the ventriculosubarachnoid space.

Erythroblastosis Fetalis and Blood Factor Rh—Six cases of fetal erythroblastosis are reported which, Kariker and Spindler state, support the thesis of immunization of the mother by the Rh agglutinin from the fetus as being responsible for erythroblastosis of the litter. Because of antepartum Rh studies on the mother of 1 of the infants, the subsequent delivery of an erythroblastotic infant was expected. The infant was treated by numerous transfusions of Rh—, anti Rh— blood. His therapy is recommended for all cases of erythroblastosis. The case of a "habitual aborter" is described in which the absence of the Rh factor in the mother seemed to be the cause of the repeated abortions. It is suggested that the term "erythroblastosis" be dropped and the conditions icterus gravis, fetal hydrops, hemolytic anemia and the like be included under the term "hemolytic disease of the newborn."

Sodium Citrate Treatment of Lead Poisoning—Kety and Letonoff used sodium citrate in the treatment of 15 adult patients with lead poisoning. The administration of sodium citrate caused a definite fall in the concentration of lead in the blood of every patient. After twenty days of citrate therapy there was no value over 0.1 mg per hundred grams. In a few patients the initial fall in blood lead was followed by a secondary rise during the course of the therapy. This rise was never great, the patients were free from symptoms during its occurrence and when the observations were continued the blood lead concentrations fell once more. Before citrate therapy the colic of 12 of the 15 patients required belladonna or opiates for its control. After citrate treatment was instituted these drugs were not necessary and abdominal pain did not recur. The one symptom that did not respond to citrate therapy was constipation. However, under citrate treatment 4 of the 7 so affected patients did improve. All patients had evidence of moderately severe anemia. In 3 of the 10 whose hemoglobin was determined before and after treatment a definite increase was shown, a slight increase in 3 and a slight decrease after citrate therapy in 4. Drugs containing iron were not used during the study. All patients experienced a definite general improvement and feeling of well being in addition to improvement in specific symptoms soon after citrate therapy was begun. No reactions attributable to sodium citrate or to lead were observed, nor did symptoms of alkalosis appear, and there was no significant change in alkali reserve or total base of the blood.

Infections of Nose and Throat in Young Adults—Rhoads and Afremow found that hemolytic streptococci were responsible for about two thirds of the attacks of tonsillitis, pharyngitis, laryngitis and sinusitis in young adults. These diseases are probably more frequent and cause more disability than any other diseases affecting this age group. The serious results of allowing carriers of hemolytic streptococci to circulate in groups of young adults, such as soldiers in barracks, is apparent. Cultures should be made in all instances of infection of the throat or the nose. Serious consideration should be given to quarantining persons harboring hemolytic streptococci in the throat or the nose or green-forming cocci in the nose.

Enterococcal Infections—Rantz and Kirby isolated enterococci from various materials obtained from more than 200 persons. Enterococci are bacteria of relatively low virulence and invasiveness but are not infrequently responsible for serious local or generalized infection. Enterococci whose normal habitat is the human bowel form a group of hemolytic and non-hemolytic streptococci of unique biologic properties and are members of the Lancefield group D. They are exceedingly resistant to the bacteriostatic action of sulfonamide compounds and are more frequently isolated from human clinical material other than the respiratory tract than any other streptococci.

Sulfathiazole Powder in Pharyngeal Infections —

Thirty-four patients with acute pharyngeal infections were treated by Freeman with topical application of sulfathiazole powder. The criteria for inclusion in the series were (1) a history of sore throat or dysphagia with or without systemic manifestations and (2) physical findings consistent with the diagnosis of acute infection of the pharynx or nasopharynx. Sulfathiazole powder was applied to the pharyngeal mucosa with a compressed air powder syringe until it thickly coated the involved areas. Nasopharyngeal applications were made through the nose or with a shortened eustachian tube catheter placed behind the soft palate. The dose varied between 1 and 2 Gm per treatment. Much of this was lost by expectoration, but examination at one, two three and four hour intervals following treatment revealed a surprisingly large amount of the powder clinging to the nasopharyngeal and pharyngeal mucosa in the vallecula and in the crypts of the tonsils. The patients were instructed to avoid eating or drinking for two hours following treatment and were told to use no other form of therapy. Subjective improvement was noted in one to twenty-four hours after the first treatment with an average of ten hours. Objective improvement was obtained in from twenty-four to fifty-six hours with an average of 24.6 hours. From one to four treatments at twenty-four hour intervals were required. Of 18 of these patients who were followed at twenty four hour intervals with determinations of the free sulfathiazole in the blood only 5 (27 per cent) showed any presence of the drug. Subjective and objective improvements were rapid especially in cases of acute nasopharyngitis. The duration of the disease was decreased considerably. In 1 case of follicular tonsillitis the patient who had received treatment returned three days later with an incipient peritonsillar abscess which was promptly aborted by sulfanilamide given orally and hot irrigations of the throat. Three patients with acute pharyngitis and coryza obtained subjective relief from their symptoms within three hours but the disease subsequently ran the course of a typical catarrhal rhinosinusitis. In 2 cases of tonsillar ulceration due to Vincent's organisms no improvement was obtained. The possibility of systemic damage from the use of sulfathiazole is negligible with this method of treatment. The method is inexpensive and is easily carried out on ambulatory patients.

Staphylococcal Meningitis Recoveries Following Bacteriophage Therapy—MacNeal and his collaborators were able to find records of only 48 acceptable examples of recovery from staphylococcal meningitis. During ten years of bacteriophage therapy of staphylococcal infections they recorded 11 recoveries from staphylococcal meningitis of which 7 are considered acceptable as recoveries from diffuse cerebrospinal staphylococcal leptomeningitis. Two of the cases have been previously reported. One patient who apparently recovered from diffuse meningitis subsequently died after unsuccessful craniotomy for an abscess of the brain and is therefore omitted from the group of valid instances of recovery. A case of local cerebral meningitis and 1 of local cervical pachymeningitis with recovery are also not included in the group of diffuse meningitis. Recovery from staphylococcal meningitis may be achieved by skilful use of bacteriophage without other therapy. The authors recommend the use of a sulfonamide drug preferably

sulfathiazole or sultapyridine along with bacteriophage. Antitoxic serum may also be added to this therapeutic combination during the first week. Bacteriophage therapy should be continued long after apparent clinical recovery in order to prevent the development of dangerous sequelae, especially abscess of the brain.

Sympathectomy in Hypertension—Bordley and his associates report the results of splanchnicectomy in the treatment of 12 patients with essential hypertension. Ten of these have been followed for three to seven years after the operation. Two died shortly after operation. The sole criterion for operation was the presence of incapacitating symptoms. In 3 patients a supradiaphragmatic splanchnicectomy (Peet operation) and in 9 an infradiaphragmatic splanchnicectomy (Adson-Craig operation) was performed. The level of arterial pressure was lowered for six to eighteen months in 4 of the 9 patients treated by the infradiaphragmatic operation and for four and one-half years in 1 of the 3 patients treated by the supradiaphragmatic operation. Symptomatic relief appeared to depend on lowered arterial pressure in 4 of 9 patients in whom it occurred. In 2 patients abnormal findings in the heart and eyegrounds regressed during the period of lowered arterial pressure and returned after the arterial pressure again rose. Return of arterial pressure to preoperative hypertensive levels was not associated with regeneration of sympathetic nerves supplying the lower extremities which were severed during the Adson-Craig operation.

Aqueous Base Yellow Fever Vaccine—According to Hargrett and his co-workers the preparation of aqueous base living yellow fever vaccine was undertaken by the United States Public Health Service in 1941. This vaccine is an aqueous extract of 10 to 11 day old chick embryos infected with the attenuated 17 D strain of yellow fever virus. It differs from the 17 D serum base vaccine extensively used in recent years in that it contains 75 per cent, rather than 10 to 40 per cent, embryo extract and no serum diluent. The extract is preserved by desiccation under high vacuum from the frozen state, with storage at subfreezing temperatures in an atmosphere of dry nitrogen. For administration the dried preparation is rehydrated and diluted 1:10 with isotonic solution of sodium chloride, with each recipient receiving 0.5 cc subcutaneously. The increased virus content of the aqueous product as contrasted with the serum containing preparation insures that a greater quantity of virus is inoculated. This favors host immunization. In excess of 600,000 doses of the aqueous type vaccine have been released to date for general use without encountering unfavorable reactions. Of 28 individuals studied, all possessed specific virus neutralizing bodies several weeks after vaccination. Danger of vaccine contamination by serum containing pathogenic agents is eliminated by this new method of preparation.

Experimental Chemotherapy of Burns and Shock—Rosenthal studied the effects of systemic therapy, employing a standardized procedure for the production of burns fatal to mice within forty-eight hours. He was concerned only with the early mortality and therefore limited his therapy to the first seven hours after the burn. He observed no benefit from epinephrine, posterior pituitary injection, adrenal cortex extract or desoxycorticosterone acetate injected subcutaneously. Sodium chloride by mouth or intraperitoneally caused a significant reduction in the mortality. Intravenous administration was less effective. Isotonic solution of sodium chloride by mouth was superior to hypertonic solutions. Potassium chloride caused an acceleration in the time of death, and when administered with sodium chloride it antagonized the effects of the latter. Calcium gluconate orally was without effect. Isotonic dextrose solutions orally showed slight therapeutic action. The administration of hypertonic dextrose solutions or water by mouth caused the animals to die faster than the controls. Sodium acetate, succinate, bicarbonate and lactate were as effective as sodium chloride. Mouse serum intravenously was slightly less active than equivalent volumes of 0.9 per cent sodium chloride orally. Little effect was observed from the intravenous administration of a hypertonic solution of human serum albumin.

Castration in Prostatic Cancer—Rupel calls attention to the fact that the prostate shrinks following castration in malignant as well as in benign hyperplasia. These end results are caused by the diminution of androgenic substance normally released by the interstitial cells. Similar results may be obtained with estrogens. When the serum level of acid phosphatase fails to fall to normal after castration, we may suspect that some other foci are producing the enzyme or that the malignant process is of the undifferentiated type. Diethylstilbestrol could be utilized for the very aged and for those who refuse to submit to castration. Its use, however, is not without some risk. Administration of diethylstilbestrol in 1 mg doses daily over a period of two months has produced distinct breast changes, pain and lumps, in 4 of 8 patients. The author excised the testes of 26 patients with prostatic cancer, 8 others received diethylstilbestrol. The symptoms of these patients varied from mild prostatism to intolerable pain, complete retention and continuous hemorrhage. With 1 exception, every patient had a definitely fixed, nodular, or flat prostate. X-ray studies of the bony pelvis, including the spine and upper portions of the femurs, were made on every patient. The King-Armstrong method was used for serum phosphatase determinations. The response to testicular excision has been the relief from pain, relief in bladder neck irritation and production of atrophy of prostatic cancer cells. Usually the prostatic atrophy becomes palpably noticeable in four months, reaches a state of fixed, smooth concavity in eight, and the gland disappears in a year. The patient has no pain, gets about well, may have some short "hot flashes," is not eunuchoid in appearance and is in good health.

Typing of Typhoid Bacilli by Means of Vi Bacteriophage—During the period from 1940 to 1942 440 strains of typhoid bacilli were examined by the Vi bacteriophage method of Craigie and Yen. Of 432 strains that were Vi forms 363 (84.1 per cent) were successfully typed while 69 (15.9 per cent) were untypable or imperfect Vi forms. The remaining 8 strains including 6 from chronic carriers could not be typed because the cultures were O forms. Most of the strains belonged to 8 of Craigie's original phage types. In addition 4 new Vi phage types were identified. The bacteriophage test is a reliable guide to the epidemiologic investigation of outbreaks or sporadic cases of typhoid. Its application greatly facilitates the detection of chronic carriers especially of those responsible for sporadic cases in endemic areas.

Tetraethylthiuram Monosulfide in Scabies—Clavton found that a 25 per cent emulsion of tetraethylthiuram had a curative effect in 11 out of 14 cases of severe and complicated scabies, the remaining 3 cases being probable reinfections. In 15 volunteers and in 18 patients the emulsion failed to produce dermatitis or irritation beyond a preliminary smarting in some severe cases. The preparation appears to have extremely beneficial results on some of the secondary concomitants of scabies. In 5 per cent aqueous solution it has proved curative in 93 consecutive cases and produced only mild dermatitis in 7 cases. It has proved to be a sarcopticide of potency against the human itch mite and is worthy of extended trial.

Flexner Dysentery—Caldwell and Hardwick review observations on 357 cases of severe diarrhea or definite dysentery occurring in mental hospitals between 1940 and 1942. In November 1941 an improved technique was adopted in the collection of fecal specimens and the desoxycholate citrate medium of Hynes was used in place of MacConkey's. As the result of these improved methods a high proportion of cases of diarrhea suspected of being dysentery (Flexner) have been bacteriologically confirmed. The majority of persons infected with Bacterium dysenteriae excrete the bacilli during convalescence and the temporary carrier state may last for several weeks. Contacts may become infected and exhibit mild symptoms or none.

Prophylactic inoculation with a B dysenteriae vaccine has not prevented infection, but it may have modified the course of the disease in some instances. The following factors are of importance in the spread of the disease: (1) failure of the nursing staff from ignorance or from a mistaken sense of duty to report gastrointestinal symptoms, (2) the common temporary carrier state following infection, (3) the occurrence or missed cases forms frustes or asymptomatic cases. Sulfanilguanidine appears to be an effective antidyenteric agent. It probably shortens the course of the disease and appears to clear the stools of B dysenteriae more rapidly than the sodium sulfate treatment. It is useful in cases of chronic diarrhea following dysenteric infection suggesting that it may be an effective treatment of the chronic carrier.

Antistreptococcal Activity of Pantoyltaurine—McIlwain and Hawking draw attention to the fact that the therapeutically successful level of sulfanilamide may or may not be inhibitory in vitro, according to the coincident concentrations of antagonistic compounds, or which p-aminobenzoate is the most important. This compound is more than a drug antagonist since it is a substance essential to animals and to bacteria. The action of sulfanilamide depends on its preventing the micro-organisms use of the p-aminobenzoate apparently by virtue of its structural similarity to p-aminobenzoate. It appeared possible that bacterial growth might be also prevented by compounds chemically related to other substances essential to bacteria such as pantothenate, which is present in the blood of animals. Several compounds structurally related to pantothenate were examined and pantoyltaurine was the most actively antibacterial in vitro preventing the growth of hemolytic streptococci when present in concentrations two hundred times those of the coincident pantothenate. Pantoyltaurine is a compound which was designed to inhibit growth of bacteria needing pantothenate by displacing it from the points at which it interacted with micro-organisms and so starving them or a substance essential for growth. Streptococcus hemolyticus was particularly sensitive to this action in vitro. Pantoyltaurine was rapidly excreted by rats but the ratio of pantoyltaurine to pantothenate concentrations in their blood could be kept above the range of in vitro action for most of the day by frequent subcutaneous doses to which there was no intolerance. Rats so treated for four days were protected from approximately 10,000 lethal doses of a virulent strain of streptococcus and less completely from 1,000,000 lethal doses. Mice whose blood pantothenate was much higher than that of the rat or of man were not protected. Sulfonamide resistant streptococci and some strains of Corynebacterium diphtheriae are sensitive to pantoyltaurine. Since the concentration of pantothenate in human blood is slightly less than that in rat blood, somewhat lower levels would be necessary for therapeutic action in man. Practical applications to human therapy may be possible along these lines but the main value of this work lies in its description of new methods for the discovery of chemotherapeutic compounds.

New Treatment of Kala-Azar in Children—Neostibosan, the preparation most widely used at present, is, according to Ramos Fernandez and his associates, difficult to preserve, it must be given intravenously, which constitutes a difficult technique to be employed for hospitalized children. The intramuscular injection often results in local intolerance, while some cases are resistant to the drug. The discovery of the hexonate of antimony (solustibosan) constituted an improvement. This substance is available in a 20 per cent oily solution or in a concentrated aqueous solution. The hexonates of antimony have a much lower toxicity than other preparations of antimony and are therefore better tolerated. The aqueous solution of the hexonates of antimony are rapidly eliminated from the organism, while the oily solution permits of slow absorption. The authors compute the total dose on the basis of 1 cc per kilogram of body weight. The total dose is divided into five fractionated doses, which are injected intramuscularly on alternate days. The maximal total dose is 60 cc and the maximal individual dose is 5 cc. For the concentrated solution the total dose per kilogram of body weight is 0.4 cc, this is divided into ten separate doses, which are injected at twelve hour intervals. The maximum total dose is 24 cc and the individual dose 2 cc. The authors present clinical histories of 7 children treated with the new preparation.

Intraperitoneal Hemorrhage Caused by Rupture of Corpus Luteum—Rincon Nuñez and Oliva Priego report the history of a woman aged 29 who was operated on for suspected appendicitis. The operation revealed an intraperitoneal hemorrhage which originated in a ruptured corpus luteum of the right ovary. Studies of serial sections excluded the existence of an ovarian pregnancy. Grave intraperitoneal hemorrhages of ovarian origin are comparatively rare. One author reports having seen only 3 cases in more than three thousand laparotomies. Infectious processes, intoxication from absorption of abortifacients, masturbation, coitus interruptus, myomas and uterine retroflexion have been suggested as possible causative factors. The quantity of blood in the peritoneal cavity varies between 200 and 500 cc but as much as 1,500 and even 3,000 cc has been reported. Microcystic degeneration of the ovaries, inflammation of the tubes, fibromatous uterus and fixed retroflexion are lesions often encountered. Some observers, particularly Forssner, maintain that these hemorrhages are invariably caused by ovarian pregnancy. To rule out this cause the extirpated ovary should always be subjected to microscopic study. In the case reported, as well as in some cases mentioned in the literature, the patients were virgins. This fact is important for the diagnosis. Symptoms of hemorrhage from ruptured corpus luteum are often mistaken for those of appendicitis or ectopic pregnancy.

- *Onset of Labor and Stimulation of Uterine Contraction by Estrogen A. Ferreira Gomez—p 23
- Lathyrism Clinical Study A. Gonzalez Paracuellos—p 46

Onset of Labor and Stimulation of Uterine Contraction—Ferreira Gomez administered intramuscularly from 50,000 to 100,000 international units of estrogen to 20 women in a state of ruptured membranes without uterine contraction or with weak uterine contractions. The results were satisfactory with all patients given 100,000 international units and in 75 per cent of those given 50,000 units of the substance. In 1 case of a hydatid mole and in 1 case of retained dead fetus intramuscular injection of 300,000 international units of the substance caused

the expulsion of the mole and of the retained fetus. The author recommends 100,000 international units as the proper dose to initiate labor or to stimulate uterine contraction when the fetus is alive. A smaller dose of the substance may fail, whereas a larger dose may inhibit secretion of milk.

- *Gigantic Pleural Emphysematous Blebs Seven Cases E. S. Mazzei—p 237
- Abortive Therapy of Furuncles and Anthrax Edmundo Escomel—p 245

Gigantic Pleural Emphysema—Mazzei reports observations on 7 men between the ages of 30 and 62 years with gigantic emphysematous blebs of the pleura. The disease involved only the right lung of 4 and the right lung predominantly with mild involvement in the left one of 3. The clinical symptoms and the roentgenologic signs of all were typical. The disease of 1 was associated with pulmonary tuberculosis, of 2 with bronchial cancer and of 1 with arteriosclerosis of the pulmonary artery (Ayerza's disease). Necropsy was performed in 3 cases. The author believes that the disease is acquired. The most frequent symptom is dyspnea of the orthopneic type. Other symptoms are those of ordinary emphysema, spastic bronchitis and pneumothorax. The x-ray shadows of intrapulmonary emphysema of moderate size show up as intrapulmonary ring shadows, whereas those of gigantic emphysema occupy the entire hemithorax and are similar to those of chronic pneumothorax. The differential diagnosis is made on the following signs: (1) The size of the x-ray shadow may increase after an attack of dyspnea and diminish after administration of bronchodilating drugs, (2) the collection of air has no proper wall in the roentgenogram. It is delimited by the visceral pleura and by a layer of collapsed pulmonary tissue, (3) iodized oil administered through the bronchi passes to the emphysema cavity only exceptionally, (4) local infection and suppuration are extremely rare. The course of the disease depends on the degree of the intracavitary air pressure, which is related to the degree of bronchial obstruction. Rupture of emphysema leads to formation of pneumothorax. Bronchodilating drugs, especially ephedrine and aminophylline, are indicated to prevent respiratory insufficiency. Removal of emphysemal air by means of repeated puncture is indicated in cases of gigantic emphysema with increased internal air pressure and threatening respiratory insufficiency.

- *Treatment of Incomplete Abortion V. Marino Donato—p 144
- Erythro sedimentation in Pulmonary Tuberculosis I. Natin and B. Rapaport—p 152

Treatment of Incomplete Abortion—Marino Donato reviews observations on 1,936 incomplete abortions treated in the maternity ward of the Hospital Juan F. Salaberry in the course of sixteen years. Authors advocating active treatment regard the product of conception when retained in the uterine cavity as a culture medium for micro-organisms and see danger in the postponement of the evacuation of the uterus. At the author's clinic treatment consists in bed rest, an ice bag to the lower part of the abdomen and quinine in doses of 0.5 Gm every hour until three have been taken. An hour after the administration of the last tablet, hypophysin is injected subcutaneously. In some cases cardiac and general stimulants are added. If the uterus is not evacuated within several days an active intervention is instituted. Between 1936 and 1941, medical treatment was used in more than 76 per cent of the afebrile cases of incomplete abortion, whereas preceding this period curettage had been employed in over 85 per cent. The superiority of the conservative over the active treatment in the febrile cases has been established beyond a doubt. The fever usually subsides in a relatively short time and spontaneous evacuation of the product of conception takes place within a few days. Afebrile incomplete abortion should be treated in the same manner.

Book Notices

Diseases of the Breast. Diagnosis Pathology Treatment. By Charles F. Geschickter M.A. M.D. Lieut. Commander Medical Corps United States Naval Reserve. With a special section on treatment in collaboration with Murray M. Copeland A.B. M.D. F.R.C.S. Instructor in Surgery Johns Hopkins Medical School Baltimore. Fabrikoid Price \$10. 1p. 223 with 193 illustrations. Philadelphia Montreal & London J. B. Lippincott Company 1913.

This is a comprehensive book on the diseases of the breast written in the light of newer knowledge of structure function and method. It is based to a large extent on observations and experiments of the author himself. The topics of the first part are the development and physiology of the breast and methods of diagnosis of mammary diseases. Then is described the breast in pregnancy and lactation with special reference to their influence on mammary lesions, particularly carcinoma and mastitis. Chronic cystic mastitis and noncancerous mammary tumors are discussed in the third and fourth parts respectively. The fifth part devoted to all phases of mammary cancer except treatment is the longest part (255 pages). The treatment of mammary tumors is described in part six. In part seven are reviewed the author's work on experimental cystic mastitis and on mammary tumors.

There are many tabulations of the results of analysis of clinical and pathologic material some of which are of little value because the social and other conditions represented by the material are not known. The effort to simplify complex problems by means of diagrams sometimes results in confusion. Most of the illustrations are original but vary greatly in quality. The magnification of the photomicrographs is not given.

The word cancer is used as synonymous with carcinoma. This is contrary to general usage e.g. American Society for Cancer Research National Cancer Institute American Society for the Control of Cancer the British Empire Cancer Campaign and *Cancer Research*.

The book contains statements and conclusions with formidable implications but inadequate proof. Thus it is stated that in certain cases of adenosis or Schimmelbusch disease the lesions disappear after pregnancy. It is potentially cancerous lesion—as many authorities believe Schimmelbusch disease to be—actually disappears after pregnancy the fact would be of the greatest importance but unfortunately proof of such disappearance is lacking. The author has included many cases without microscopic proof hence the nature of many lesions remains in doubt and it is probable that patients whose breasts improved after pregnancy were suffering from physiologic states which regress spontaneously and not from Schimmelbusch disease.

The author arrives at the important conclusion that no etiologic relationship exists between chronic cystic mastitis and carcinoma and thus places himself in direct contradiction with an increasing body of opinion (Ewing McCarthy Konjetzny Semb Cheate Cutler and others). Warren's recent statistical studies also are opposed to the author's conclusions. Cheate's extensive studies of the breast by means of whole serial sections are opposed to the conclusions of Geschickter who did not examine his specimens by Cheate's method. The fallacies in the author's presentation of precancerous lesions are obvious for the following reasons: 1. Large numbers of cases (as high as 70 per cent in some categories) are without microscopic proof under circumstances in which an accurate clinical differentiation between such conditions as mastodynia adenosis and so called chronic cystic mastitis is not possible. 2. The average duration of the follow up (10.2 years) is inadequate and by no means excludes the later development of cancer in a certain proportion of the patients. 3. Many patients who are reported well after local excision of the lesion and even after mastectomy are cited as proof of the innocent nature of the lesion but obviously many such cases are examples of surgical cures of potentially cancerous lesions. 4. Under the term chronic cystic mastitis the author includes lesions which are physiologic and certainly innocent with lesions such as Schimmelbusch disease which are distinctly pathologic and menacing. To group such

a variety of lesions in unknown proportions and often without microscopic proof in a statistical analysis is unsound, and to draw the conclusion from such a study that these various conditions are not etiologically related to cancer is obviously unwarranted. Before accepting the conclusion that cysts, papillomas and Schimmelbusch disease are innocent lesions, the physician should weigh the author's evidence against the formidable body of opinion which holds the opposite view.

The pathologic classification of mammary cancer adds further confusion in a field already hopelessly confused. Meaningless names are given to microscopic appearances of fragments of tissue from the breast when it is well established by means of whole serial sections that several or all of such appearances may be present in the same breast.

In his experimental work the author produced lesions in the breast of the rat which seem to be comparable morphologically with lesions in the human breast but he has oversimplified the mechanism of formation of the lesions and assumes an analogy between the two with unwarranted positiveness. The suggested endocrine treatment of various lesions of the human breast is without adequate basis. Thus on page 64 the author admits that testosterone does not act in the same manner in man as in the rat yet throughout the book he draws conclusions that the effects of testosterone are similar in the rat and in the human female breast and suggests endocrine therapy on this basis.

Preventive Inoculation. By W. Powell Phillips M.R.C.S. L.R.C.P. D.P.H. Deputy Medical Officer of Health Cardiff and C. Woodroffe Anderson M.B. Ch.B. D.P.H. Assistant Medical Officer of Health Cardiff. With introduction by J. Greenwood Wilson M.D. F.R.C.P. D.P.H. Medical Officer of Health Cardiff. Cloth Price 6s. 6d. Pp. 74. London The Practitioner in conjunction with Eyre and Spottiswoode 1912.

This little volume is the seventh of a series of handbooks published by the *Practitioner* and designed as practical guides for the busy physician. The first part of the book discusses in elementary style the basic principles of infection and immunity and their application in the prophylaxis of disease. There follows a simple statement of technique of injection and apparatus required. In the remaining two thirds of the volume the authors describe briefly immunization against diphtheria tetanus scarlet fever typhoid and paratyphoid fevers whooping cough measles influenza and the common cold. A final chapter describes immunization against other diseases a few lines being given respectively to tuberculosis plague typhus fever cholera dysentery yellow fever poliomyelitis cerebrospinal meningitis anthrax and pneumococcal pneumonia.

This is strictly a handbook for the practitioner who has no time to read the standard textbooks of preventive medicine or bacteriology. The discussions of the various procedures are too brief and elementary to satisfy the needs of the medical student who must be more thoroughly trained in basic principles.

The American reader will note references to antigens not used in this country such as toxoid antitoxin floccules and the new alcohol killed typhoid vaccine of Felix. He will wonder at the suggestion that women should be given smaller doses of typhoid vaccine than should men. It is not clear why the authors chose to ignore the typhoid studies of Siler and his colleagues at the Army Medical School. Similarly it is surprising to note the statement that for yellow fever immunization one should inject a small quantity of immune human serum a few hours before administering the vaccine. It may be wondered why the authors fail to mention the newer yellow fever vaccines in general use for over five years.

Burns Shock Wound Healing and Vascular Injuries. Prepared under the auspices of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. *Military Surgical Manuals* Volume V. Cloth. Price \$1.50. 1p. 272 with illustrations. Philadelphia & London W. B. Saunders Company 1913.

This is the fifth of the series of six military surgical manuals and covers the management of the several wartime emergencies indicated in the title. Despite the variety of the material covered the general standard of the book is high and this volume compares favorably with the other volumes in the series. In fact the subjects covered especially burns and shock repre-

sent especially important aspects of present day military medicine. Each of the four chief sections of the book represents a discrete condition and should be considered separately.

The section on burns, covering 103 pages, divides the discussion into general management, local care, early plastic care and late plastic care. In addition there is a good short but incomplete and overcondensed account of the management of burns received in chemical warfare by Dr David P Barr. In this chapter only three of the gases are considered and no mention is made of phosphorus, magnesium or other burns due to metals, which are so important in the present war. The first chapter, on the general management of burns, by Dr Henry N Harkins, rightly emphasizes the especial importance of plasma administration in the control of burn shock. Drs Roy D McClure and Conrad R Lam discuss the local care of burns and cite the advantages and limitations of the tanning, pressure dressings, sulfadiazine spray and other methods. Drs McClure and Harkins in a third chapter from the Henry Ford Hospital group discuss the early plastic treatment and care of amputating surfaces. They cite the importance of early skin grafting and point out the particular military applicability of the Padgett-Hood dermatome for this purpose. The next chapter, on the late plastic care, by Dr James B Brown, represents one of the best accounts of the subject in the literature and is remarkable for the excellence of the illustrations.

The second section, on shock, is divided into three chapters: mechanism, by Dr Norman E Freeman, prevention and treatment, by Dr Alfred Blalock, and fluid replacement therapy, by Dr Max M Strumia. In a space of 67 pages these authors have written what is, in the reviewer's opinion, the best account on shock extant. The only possible criticism of this section is that it is not graced by the presence of a bibliography. Since the military surgical manuals will undoubtedly be studied at base hospitals in this country as well as at the front, it seems that a brief bibliography would be desirable.

The short (17 pages) third section, on wound healing, by Dr Allen O Whipple, is beyond criticism.

The fourth section, on vascular injuries, is written jointly by the subcommittee of the National Research Council on that subject, composed of Dr John Honians, chairman, and Drs Arthur W Allen, Geza de Takats, Daniel C Elkin and Walter G Maddock. The material occupies 64 pages and considers control of hemorrhage, injuries to arteries, diseases of arteries and diseases of veins. The use of heparin in vascular surgery is cited, but the book was apparently written too early to describe some of the most recent developments in arterial anastomosis. The section on injuries to arteries in special locations includes a very helpful account of the anastomoses in each location with excellent diagrams. The role of sympathetic block in vascular surgery is adequately presented along with several illustrations of great merit. Finally, the ever practical subject of varicose veins is competently delineated.

This book is to be recommended not only to military surgeons but to those in civil life as well, both practitioners and medical students.

Etapas de la vida médico patriota del doctor Juan Madera procer de Mayo Por Luciano Abeille. Second edition. Paper. Pp 324, with illustrations. Buenos Aires, 1942.

For the historian concerned with the rise of modern medicine in South America this book will be an invaluable document. From it we learn about the life of Dr Juan Madera, born in Buenos Aires in 1782, physician and patriot, head of the first medical military unit and of the first institution of sanitary police of Argentina, first professor of therapeutics, physician of the Hospital for Foundlings, member of the first Academy of Medicine of Buenos Aires. However, his most important contribution was the introduction of jennervian prophylaxis in his country, for which he was appointed first "administrator of the vaccinia." The virus was imported from Rio de Janeiro in 1805 by three slaves previously inoculated, and the practice of vaccination spread rapidly. Madero propagated the virus through cows and was himself responsible for isolating a strain of cowpox in his country. The Englishmen whom he fought

in his youth as a soldier and a military surgeon later rewarded his efforts by nominating him honorary member of the London Vaccine Institution. Abeille's book can hardly be called a biography. It is rather a complete compilation of documents—many of them direct reproductions of the originals—concerned with the manifold episodes of Madero's picturesque life. With these abundant data the reader is left free to speculate at will on the man and on his surroundings, and the sight of the beautiful, romantic painting of Dr Madero himself reproduced on the first page of the book is certainly an invitation to do so.

Food Poisoning By G M Dack, Ph.D., M.D. Associate Professor of Bacteriology, the University of Chicago. Cloth. Price, \$2. Pp 138. Chicago: University of Chicago Press. London: Cambridge University Press. 1943.

This volume carries on the tradition begun in the University of Chicago, Department of Bacteriology, by Prof E O Jordan, who devoted himself particularly to the salmonella type of infection. In the present work the various chapters cover chemical poisoning, poisonous plants and animals, botulism, staphylococcus food poisoning, salmonella, streptococci and other bacteria. The final chapter relates to infections which must be differentiated from food poisoning, such as the dysenteries and trichinosis. The work is succinct, accurate and up to date, offering in brief scope what every doctor should know on this subject. The American people preserve immense amounts of food, at least fifteen million families do some home canning. The hazards and the standards are fully elucidated in this book.

Diccionario de términos y expresiones hematológicas Por el Dr. Leopoldo Cea. Paper. Pp 355. San Salvador, El Salvador: C. A. Imprenta Nacional. 1941.

In this dictionary the author has collected the terms associated with hematology, providing for each a definition as well as some brief notes regarding etymology. More than a thousand words are included, which is an indication of the rapid rise of our knowledge of hematology in recent years. One would have expected a reference to the sedimentation test, which, however, does not appear. The names of a few leading workers in the field are included, but many an important investigator is omitted.

Twenty-First Hospital Yearbook 1943 Hospital Purchasing File Directory of Hospital Products Manufacturers' Catalogs Editorial Reference Section Twenty-First edition. Cloth. Price \$2.50. Pp 1 023 with illustrations. Chicago: Modern Hospital Publishing Co. Inc., 1943.

The contents of this useful book include the catalogues and advertisements of many sources of supply for practically every thing used in the hospital. The manufacturers' catalogues are classified under clinical and scientific, general furnishings, food service, laundry and construction. An editorial section includes timely articles on wartime activities, the hospital pharmacy, other administrative data, and a preview of postwar hospital and medical planning.

Influencia del equilibrio ácido básico en la reactividad cutánea. Estudio experimental en hombres Por Arturo Manrique Mera. Tesis. Universidad nacional de Buenos Aires, Facultad de ciencias medicas. Paper. Pp 50 with 11 illustrations. Buenos Aires: Imprenta de Alfredo Frascoli, 1942.

The author describes experiments carried out in man tending to prove that the skin reactions brought about by local applications of dinitrochlorobenzene are enhanced in patients subjected to an alkalosis producing diet, and diminished in patients under an acidosis inducing diet. Work leading to analogous conclusions by previous workers and contributions on allied topics are thoroughly reviewed.

El bocio tóxico Por Jose Alberto Caeiro. Paper. Pp 119 with 22 illustrations. Buenos Aires. 1942.

An excellent short monograph on goiter, the surgical aspect being specially emphasized. Yet, in the preliminary chapter, the anatomy and physiology of the thyroid gland are summarized but clearly described and the clinical symptoms in the different forms of glandular dysfunction are dealt with in some detail. For this reason the book will be advantageously read both by the medical student and the general practitioner as well as by the specialized surgeon. The photomicrographs are excellent.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PHYSICAL EFFICIENCY AND TOBACCO SMOKING

To the Editor—Is there any scientific basis for the popular belief that smoking causes shortwindedness? If so what are the physiologic mechanisms involved?

Lieutenant (MC) U S N R

ANSWER—A lowering of physical efficiency has been reported during and immediately after the use of tobacco in a number of studies which have been summarized in the extensive reviews Tobacco and Physical Efficiency by M. V. O'Shea (New York: Macmillan Company, 1923) and Tobacco and Human Efficiency by Schrumpt-Picron (New York, Paul B. Hoeber, 1927). Diminution in muscular capacity as measured with the ergograph was reported by W. P. Lombard (*J. Physiol.* 13:1, 1892) and many though not all, later workers, and fatigue was reported to commence earlier and the output or work diminish (Houghlin *J. Physiol.* 5:240, 1901 and Baumberger, J. P. Perry E. E. and Martin, E. G. *J. Indust. Hyg.* 3:1, 1921). But it is particularly the shortwindedness and lowering of respiratory reserve that has led most coaches and physical directors to insist that smoking be restricted, at least during the season of competition (Pack, F. J. *Pop. Sci. Month.* 81:330, 1912). More than a third of the subjects of a blindfold test reported 'shortness of breath' which they ascribed to the smoke (Bogen Emil. The Composition of Cigarettes and Cigarette Smoke, *THE JOURNAL* Oct. 12, 1929, p. 1110).

The carbon monoxide in tobacco smoke is insufficient to exert much effect in this regard (Hanson, H. B. and Hastings A. B. The Effect of Smoking on the Carbon Monoxide Content of Blood *ibid.*, May 13, 1933, p. 1481). The various irritating substances in tobacco smoke contribute to pharyngeal inflammation and an annoying cough more than to actual decrease in vital capacity (Bogen Emil. *California & West Med.* 45:342 [Oct.] 1936). Most of the shortness of breath reported by smokers appears to be due to the effect of the nicotine in the smoke on the heart and the circulation (Parkinson, J. and Koetod, H. *Lancet* 2:232 [Aug. 18] 1917). An accelerated pulse beat, an exaggerated sinus arrhythmia and the occurrence of premature contractions may result from the action of the nicotine on the innervation of the heart. The more alarming pain on exertion, or tobacco angina pectoris, in heavy smokers has been ascribed to coronary contraction resulting from nicotine (Vaquez, H. Diseases of the Heart, translation, Philadelphia: W. B. Saunders Company, 1924). This has been questioned by others (White, P. D. and Sharber, Trimble. Tobacco, Alcohol and Angina Pectoris, *THE JOURNAL*, March 3, 1934, p. 655) and the resulting coronary insufficiency sharply distinguished from true coronary occlusion (Masters, A. M. Carroll H. H. and Andrews, Cecil U. S. *Nat. Med. Bull.* 40:810 [Oct.] 1942).

That excessive smoking interferes with athletic prowess and may bring on shortness of breath is generally admitted (Fisher G. J. and Berry, Elmer. The Physical Effects of Smoking 1932). The differences, though distinct, are not great enough to erase all differences in native ability, and so we find that some athletes have actually succeeded in attaining distinction in spite of the persistent use of tobacco although their number is much less than might be inferred from advertisements. Although a number of physiologic mechanisms have been presented to account for the total effect observed, their relative importance and true relationship to the entire phenomenon may still repay further investigation.

REPEATED ADMINISTRATION OF TETANUS ANTITOXIN

To the Editor—In *The Journal* April 3, 1943, page 1157, in the editorial comment on 'Tetanus in the Middle East' it is stated that each wounded man is given a dose of 3,000 international units of tetanus antitoxin. Further weekly doses of the antitoxin are given to the patients who have not been actively immunized. Is it safe to give further doses of antitoxin to patients at a time when reaction may be expected to occur? Could a second skin test be depended on to warn of danger?

M D Pennsylvania

ANSWER—Injection of antitoxin at intervals of not more than seven days is regarded as safe. Induced serum disease as a rule does not manifest itself earlier than nine days or so after injection of serum. The object of injecting tetanus anti-

toxin under the circumstances is to prevent tetanus and because tetanus is almost always fatal one is justified in trying to prevent it to take some small risk of causing a form of serum disease which is not dangerous to life. Repeated injections at weekly intervals are necessary to maintain a satisfactory antitoxin level in the patient. A positive skin test would, of course indicate established sensitivity to the antitoxin.

CONCENTRATES OF VITAMIN D AND ARTERIOSCLEROSIS

To the Editor—A visiting physician expressed the opinion that vitamin D if taken in concentrated form, can lead to arteriosclerosis even in infants. I am considerably perturbed because when volunteering my services to the Army Medical Corps the month of Pearl Harbor I was turned down the reason given being early arteriosclerosis of my lower extremities as demonstrated by x-rays. I was then 47. Furthermore my children are aged 21, 19 and 16 years and 16 months respectively. For many years I have prescribed cod liver oil usually in concentrated form for a number of patients and all the members of my family have taken it faithfully. Since plain and fancy preparations of the oil itself are quite messy and unpleasant and since the concentrated forms of cod liver oil are quite the reverse please inform me authoritatively whether it is unwise to use the concentrated form of cod liver oil. M D Kentucky

ANSWER—Extremely large doses of activated sterols or of fish liver oils may produce calcification of the soft tissues including the aorta and arteries in experimental animals and in human subjects. This effect is associated with the 'calcemic' principle of the products and is not necessarily proportional to their antirachitic activity and has nothing to do with vitamin A activity. The effect is accompanied by other manifestations of toxicity: anorexia, vomiting and loss of weight.

The doses which have produced abnormal calcification have been about five thousand times those recommended for prophylaxis or rickets in normal animals, but doses only about a hundred times the prophylactic dose may produce symptoms in persons with renal insufficiency.

There is no evidence that concentrates of cod liver oil are more toxic than equivalent doses of the oil and no evidence that ordinary prophylactic doses of either will produce arteriosclerosis.

SEVERE CHRONIC CONSTIPATION

To the Editor—A woman who suffers from chronic constipation sometimes to the extent of going five and six days without a bowel movement is most desirous of finding a more normal and natural method of handling her problem than resorting to the use of laxatives and enemas. The constipation seems to be of the atonic type as the only laxative which seems to be of any value is a combination of aromatic cascara and physostigmine. The movement is usually small in amount, hard and dehydrated and dark brown. Please inform me if there are any exercises or calisthenics which would increase the tone of the colon. Any other suggestions you have will be appreciated.

Lieutenant M C A U S

ANSWER—A person suffering from chronic constipation of this type should have a basal metabolic test to see whether or not hypothyroidism is not an important etiologic factor. It is present $\frac{1}{2}$ to 1 grain (0.03 to 0.06 Gm.) of thyroid three times a day may relieve the constipation. If the basal metabolic rate is within limits of normal, the constipation is probably on a psychogenic basis. I would suggest that the patient consult a neuropsychiatrist for this hypothetical approach. Most functional disturbances of the colon are of neuropsychiatric origin.

BRONCHOPNEUMONIA AS CAUSE OF DEATH IN EARLY INFANCY

To the Editor—In the following cases bronchopneumonia was given on the death certificate as the only cause of death. The age and the date of death were: 1. 1 day June 22, 1942; 2. 1 day July 8, 1942; 3. 1 day August 16, 1942; 4. 3 days October 17, 1942; 5. 27 days October 12, 1942. These questions automatically arise: 1. Is it possible for bronchopneumonia to be the primary cause of death in the first week of life? 2. Is it possible for intrauterine bronchopneumonia to develop in the last month of pregnancy with no signs of symptoms of pneumonia in the mother?

William C. Buss, M.D. Bakersfield, Calif.

ANSWER—1. It is possible for bronchopneumonia to be the primary cause of death in the first week of life. A number of such cases occur both in premature and in full term infants in whom the larynx and trachea have been traumatized by the passage of a tracheal catheter and in others as the result of aspiration pneumonia. The difficulty in making a diagnosis of bronchopneumonia rather than pneumonia alone naturally is open to question.

2. It is certainly possible for intrauterine pneumonia to develop in the last month of pregnancy without the mother giving signs of circulatory infection from which source it must have derived. On the whole this could be considered an uncommon cause.

UNCLASSIFIED GLYCOSURIA OR DIABETES

To the Editor—A man aged 35 first had sugar in his urine fifteen years ago. Since that time he has consistently had sugar in his urine specimens. His general health has been excellent. His laboratory findings were as follows:

Dextrose (100 Gm) Tolerance Test

Time	Specific Gravity	Sugar in Urine		Sugar in Blood Mg./100 Cc
		Qualitative	Per Cent	
0	1.031		0.3	105
15 minutes				147
30 minutes		+	0.7	133
45 minutes				183
60 minutes	1.040	+	2.0	187
75 minutes				175
90 minutes				175
105 minutes				179
120 minutes	1.040	+	2.25	172
150 minutes				161
180 minutes		+	1.1	94

Should this patient be on a restricted diet or should the presence of sugar in the urine be ignored?
M.D., Connecticut

ANSWER—Further information is necessary before one should attempt a diagnosis.

1. Was the dextrose tolerance test carried out after an all night fast or at least five hours or more after food? 2. Was the patient free from infection as proved by temperatures taken at the beginning and end of the test? It is assumed that he did not have chronic arthritis or hyperthyroidism. 3. What method was used for the estimation of the blood sugar? 4. Are the data based on capillary blood from the ear or finger or on venous blood? Values for capillary blood are higher than for venous blood taken simultaneously save in the fasting state. An example follows:

	Fasting	1/2 Hr.	2 Hrs.	4 Hrs.	5 Hrs.
Capillary	95	204	150	98	80
Venous	91	156	120	76	74

It is a safe rule not to diagnose diabetes by capillary blood after food unless the value reaches 200 mg or more in contrast to 170 mg by venous blood. If the bloods in this case were capillary bloods, the patient would not be considered diabetic, but by venous blood the diagnosis would be diabetes.

Tests of the urine all indicated the presence of sugar even though certain blood sugar values were normal. It is unjustifiable, however, to assume that true renal glycosuria is present, because it is not stated whether the bladder had been emptied an hour or more before the first test. The 0.3 per cent sugar in the fasting specimen might have passed into the bladder several hours previously, and likewise at 180 minutes the 1.1 per cent sugar in the urine with a blood sugar of 94 mg would not prove renal glycosuria, because only one hour before the urine contained 2.25 per cent sugar and the sugar might have been passed into the bladder after that.

Irrespective of the diagnosis, whether unclassified glycosuria or diabetes, it is obvious that such a patient should be watched for life, although it is the exception for borderline cases such as this to change their status. The patient should not expose himself to diabetes by a gain in weight or by indulgence in a rich carbohydrate diet or conversely by imposition of a low carbohydrate diet.

PERFORATION OF DRUM MEMBRANE AND EXPOSURE TO NOISE

To the Editor—It is my impression as an industrial physician that a person with chronic active otitis media with perforation of the tympanum and moderate drainage should not be permitted to be exposed to repeated loud noises such as one might encounter in a riveting operation. It is also my impression that a person with arrested otitis media with a perforation of the drum but no discharge but with a history of discharge within the past five years should not be placed on riveting. I am unable, however, to find a reference that would substantiate this opinion. I should like an opinion on whether such restriction on employment is reasonable.
M.D., New Jersey

ANSWER—Perforation of the drum membrane with or without discharge would not make an ear more susceptible to acoustic trauma from riveting but would rather protect the ear, since the impairment of sound conduction resulting from such a perforation or otitis media diminishes the volume of sound reaching the nerve of hearing and acts exactly the same as a tight plug in the ear canal. Therefore there is no reason to restrict the employment of such persons or to avoid riveting.

SYPHILIS AND NEPHRITIS

To the Editor—A white man aged 32 was rejected by the army in January 1942 because of a positive Wassermann reaction. Two subsequent serologic tests were positive. He admitted exposure but had no knowledge of symptoms or signs of syphilis. In 1934 he was sick for a few days with the grip. In 1936 he had a sore throat for three days; the doctor consulted suggested tonsillectomy. In 1937 he passed on examination for life insurance. The only complaint is slight backache. Physical examination discloses nothing abnormal. The age, height and weight ratios are correct. The blood pressure is 120/78. The cardiovascular system, the reflexes, the abdomen, the lymph nodes (except in the cervical region) and the spinal fluid are normal. A blood count showed 7,100 white blood cells and 77 per cent polymorphonuclears, the hemoglobin was 80 per cent (Sahli). The phenolsulfonphthalein response was excellent. The prostate was normal. There was slight to 4 plus albumin in the urine and the specific gravity range was from 1.006 to 1.024. In the beginning, red blood cells were found and a few hyaline and granular casts. Two dead teeth were extracted, later an tonsillectomy was performed because the tonsils looked suspicious. A consultant urologist found the genital urinary tract normal. A small polypus of the bladder was cauterized, and since then the red cells have almost disappeared but albumin and infrequent granular casts are still found. A series of bismuth sub salicylate and mapharsen, small doses of each, including potassium iodide, has been given for some months. Full details relative to diet, rest and hygiene have been planned. The patient looks well and has no complaint. The question arises whether to continue with small doses of the drugs or in view of the urinary findings, to forego specific treatment and wait for the kidneys to improve? Will you please advise me with regard to this case?
M.D., Virginia

ANSWER—The onset of an acute nephritis in a patient who has early syphilis is an extremely rare complication. Such a nephritis is evidenced by varying degrees of edema and the presence in the urine of large amounts of albumin and small numbers of casts and blood cells. The edema and urinary findings usually disappear rapidly following the administration of small amounts of arsphenamine and bismuth.

Syphilis of the kidney as a complication of late syphilis is practically unknown, at least it is impossible to differentiate it from the common types of nephritis as seen occasionally in cases of syphilis.

In the case under discussion evidence is not available apparently to determine the duration of the syphilis, and the basis for the diagnosis of syphilis appears to be on only the serologic evidence. It is not stated whether the serologic reports were all strong positives or were of a questionable positive nature, and thus the question is raised as to the authenticity of the diagnosis of syphilis. If the diagnosis is still justified by repeated strongly positive serologic reports obtained from different laboratories on the same specimen of blood, it would then seem advisable to treat the patient for syphilis and nephritis simultaneously. The use of mapharsen and bismuth compounds in smaller doses than usually given a young man would be justified. The spinal fluid should be examined to determine whether there is need for intensifying the treatment, if and when possible. Such dietetic and other measures as are indicated for the nephritis should be employed concurrently. Under such a program urinary findings of the type described usually disappear, however, the patient must be kept under close surveillance to make certain that the kidney damage is not extensive and of a permanent nature.

REMOVAL OF FISH HOOKS

To the Editor—I was much interested to read in *Queries and Minor Notes* Department in *The Journal*, May 22, 1943, page 268, the discussion about fish hooks. My office and house are surrounded by wharves, beaches and cliffs, all giving access to the Atlantic Ocean and amateurs come from New England's industrial area to leave fish hooks, ashore and afloat. On the theory of chance, a certain number of hooks end up in human flesh usually in *persona propria* but frequently in *alter*. The presence of the hook is a psychologic as well as a physical hazard and everybody goes to work to extract it. There are two schools of thought—the "push 'em out" school and the "pull 'em out" school. How many of these subscribers to either of these techniques are successful, I do not know because I never see them. I believe they are few or none. The ones I see are those who are in shock as the result of one of their misguided enthusiasms, with the hook still in. I should like to recommend a little 2 per cent procaine hydrochloride alongside the shaft, a rubber band or a tourniquet an incision parallel to the shaft with a wide blade along the barb, and out comes the hook with a wide, cleanly incised wound behind to treat according to one's fancy and in the latest style. These wounds never get infected, never fail to heal nicely and the patients are greatly surprised. With all these questionnaires as to specialty, I have often thought of answering fish hooks. It certainly would be no more silly than some of the others. But I think I would have to take a trip to the Grand Banks really to qualify as a specialist. If Kipling was right the technic is the same minus the anesthesia but not the "push 'em out" or "pull 'em out" business—that would be too heroic for even the "Captains Courageous."
Edward M. Cook, M.D., York Harbor, Me.

ROCKY MOUNTAIN SPOTTED FEVER

GEORGE E BAKER, M D

CASPER, WYO

Western physicians are offered an unusual opportunity for study of Rocky Mountain spotted fever, one not commonly extended their colleagues in other sections of the country. Since identification of the first cases of the disease in the East shortly more than a decade ago, tick fever has stimulated additional interest among members of the profession from year to year because of the apparent rapid dissemination throughout our nation. Those in practice elsewhere are for the most part unfamiliar with manifestations of the disease. There is a distinct obligation to furnish them with accurate information regarding it. The subject of tick fever is an extensive one. No attempt should be made in a single article to deal with its numerous phases but rather to select those of major importance and to present material for further thought and consideration on a disease entity which can in time assume proportions of grave national significance.

Tularemia and tick fever are two diseases which have been dealt with from beginning to end by American investigators. More concisely, the latter condition has been dealt with almost in its entirety by those of the West. The risks run and sacrifices made by Dr Walter Reed and his associates during their yellow fever studies are noteworthy. The ones of Dr Howard Ricketts, his colleagues and contemporaries in their tick fever researches are equally outstanding. Unfortunately they have never received the recognition to which they are rightfully entitled. It is felt by some that in the future the name Rocky Mountain spotted fever as it applies to the disease will of necessity be changed. It is nationwide in distribution and carried by numerous species of ticks besides wood ticks. Although we commonly refer to the disease as "tick fever" for the sake of brevity the present accepted terminology of Rocky Mountain spotted fever serves to identify it among medical men and to honor the original investigators forever in the pages of American medicine.

It is not known whether tick fever was originally a disease of the eastern and southeastern sections of the country, carried from there westward by emigrants in their heterogeneous wagon trains, or one of the West carried eastward by more rapid means of communication at the turn of the present century. It is a rickettsial infection, closely related in many respects

to typhus fever a disease generally conceded to have been existent in certain parts of Europe and Asia for countless centuries. It is believed by most that tick fever was never absent from the Western states.

Prior to entrance of white men into the Rocky Mountain regions, references made to the disease by resident Indian tribes although legendary were nevertheless prevalent. It is probable that tick fever was endemic in localities where the savage nomads resided because they carefully avoided infested regions as much as it was possible for them to do during tick seasons. Early explorers stated that medicine men related to them the Great Spirit would not allow travelers to enter much less traverse certain sections of His domain during the spring and early summer months. To do so invited His displeasure, manifested by illness and possible death. Subsequent investigations have shown the forbidden regions to be ones where the disease has apparently been prevalent from time immemorial. Lewis and Clark made no mention of a disease entity simulating tick fever or of ticks during their extensive wanderings in the western country. They passed through and camped in several infested localities at the optimum time of year. In other respects they kept rather complete and comprehensive records of their travels.

Other explorers did not tell of the disease. It is assumed that they were unfamiliar with its manifestations. It was not until Mormon emigrants traveled overland to Utah and gold seekers to California that the first comprehensive references to conditions simulating tick fever began to appear. Army surgeons stationed at the various frontier posts came in contact with the disease. They apparently confused it with conditions known to them in the East, altered in the raw western country by climate and environment.

Pioneers of the medical profession in the unsettled West were primarily workers. Not being recorders they left little information for posterity on tick fever. Over a period of many years most of them were not aware that a new disease entity had been encountered. In time observant physicians practicing in heavily infested areas came to recognize that they were encountering a strange disease or group of diseases.

Progress in knowledge of tick fever was slow and tedious, observations on the disease often being confusing and contradictory. It was not until residents of the Bitter Root Valley of Montana began to doubt the expressed theory that it was caused by drinking snow water which had flowed through decomposed sawdust and to suspect wood ticks as vectors that tangible information was sought. A series of brilliant studies were undertaken. They revealed that tick fever was due to bites from infested wood ticks and isolated the causative micro-organism. Pamstaking investiga-

Read in part before the regional meeting of the American College of Physicians Great Falls Mont May 1 1943
Drs. R R Spencer R R Parker G E Davis H R Cox and N H Topping of the National Institute of Health Dr N H Savage epidemiologist of the Wyoming State Health Department and others lent material and gave helpful suggestions making the preparation of this paper possible

tions followed. They were successful in establishing other important features of the disease so that in time a clear concept of its many phases resulted.

As the western country became more populated, the number of cases of tick fever increased at an alarming rate, finally threatening to decimate certain sections of the newly won virgin territory. A laboratory was established for the purpose of further studies on the disease at Hamilton, Mont., in the center of the western endemic area, the site selected being one where need for added investigations appeared to be most acute. In time the laboratory was taken over by the United States Public Health Service and from a humble beginning it has grown to the modern, up to date and scientific institution with which we are familiar. The outstanding investigators in the Division of Infectious Diseases of the National Institute of Health have given us most of our present knowledge on tick fever and tick borne infections in general, as well as a great deal that pertaining to other rickettsial diseases, notably typhus fever and allied conditions.¹

The cause of tick fever is generally agreed to be a micro-organism, *Dermacentor andersoni rickettsii*. It is a gram negative Rickettsia, best identified in infected tissues by means of modified Giemsa's stains. Rickettsias are small, intracellular, coccoid or bacillary bodies observed in the tissues of infected animals. They were first described in typhus fever by Ricketts, who succumbed to the illness and in whose honor they received their name. Rickettsias can be cultivated on living tissues. To the present, attempted growth on mediums free from living cells has met with failure. They probably represent a new type of micro-organism, bacterium-like in character, displaying the same characteristics of staining shown by spirochetes. It is possible that rickettsias are pathogenic organisms adapted to insect life and peculiar to insects.

They are most difficult to study because of their minute size. In ticks rickettsias undergo a morphologic sequence indicative of a life cycle. They multiply within nuclei of cells and in cytoplasm. In human tissues they exist mainly as relatively large, deeply stained lanceolate forms in pairs, measuring approximately 1 micron in length. Three definite types are recognized in ticks. They are seen early in the infection as faintly staining rods without granules. Minute rod-like bodies are later seen, displaying chromatoid granules. The third forms are relatively large and lanceolated, being similar to those found in mammalian tissues. It is possible that the micro-organism is passed between hosts in this form.

Dermacentor andersoni, the wood tick, is the vector of tick fever in the western endemic areas. It is a three host blood sucking tick. Blood is probably its only food. Three meals are necessary for it to complete a life cycle. Blood ingestion stimulates metamorphosis

of larval into nymphal forms, nymphal into adult forms and brings about fertilization and egg laying in adult female ticks.

Female meet male ticks while feeding on larger wild or domestic animals. Following feeding, impregnation occurs. Female forms become enormously engorged, owing to the presence of ingested blood. In nine days they drop to the ground and hide away. Seven days later they begin to lay eggs at the rate of 300 a day. The eggs accumulate in a pile. The process takes a period of three weeks, during which time 2,000 to 7,000 eggs are laid. After an incubation period of thirty days they hatch into small six legged larval forms, which crawl to a convenient bush, weed or clump of grass, there lying in wait for small rodent hosts. They commonly attach themselves around the eyes or ears of the animals, partake of blood meals and after a period of six days fall to the ground and hide away. They molt into somewhat larger forms, the eight legged nymphs. Feeding and change take place in the midsummer months.

Nymphal forms lie dormant until spring. With advent of warm weather they seek similar vantage points, there lying in wait for rodent hosts. Following attachment they feed for a week, drop to the ground, hide away for three weeks and molt into adult male and female forms. By the time adult ticks have made their appearance it is too late in the season for them to seek hosts. They hibernate until spring, at which time they seek vantage points and lie in wait for larger wild or domestic animals. After attachment has occurred, the life cycle begins anew.

Tick fever is not a disease primarily of human beings but is one of animals and would exist if the former were eliminated from the picture. Ticks are not parasites of the human race. When individuals are bitten, the occurrence is purely an accident.

In the western section of the country the tick season begins early in the spring, usually around the middle of March. It continues for approximately three and a half months and tapers off around the first of July. The appearance and disappearance of ticks is governed by conditions of moisture and temperature. They may appear earlier one season than another and likewise disappear earlier. If adult ticks do not find hosts the first year, they hibernate through the winter and try the following spring. If they fail to find hosts at that time, they again hibernate and try again the second year. It is not unusual for them to survive at least four years when hosts are not found in the interim.

Wet damp weather makes ticks less active. As a result they are less apt to seek hosts. Warm dry weather brings them into full activity, so that they attach themselves readily. When ticks emerge in the spring from hibernation, their virus virulence is low. If subjected to incubation or allowed to ingest blood, they gain the ability to bring about frank infections. The phenomenon is called "reactivation." It accounts for the observation that but few cases of tick fever are seen for a variable period of time following appearance of ticks in the spring. After they have lain dormant all winter the infectiousness of virus carried by them is at a low ebb. With advent of warm weather the vectors become activated and quickly infectious. As a result, the number of cases of the disease increase as the season advances. In any locality tick fever can occur in the colder months of the year, granted that there is an abundance of warm sunshine or adequate cover.

tions of artificial heat. These factors release ticks from their dormant state, reactivating them so that they move about in search of hosts.

During cold months of the winter nymphal and adult forms lie in hibernation under decaying vegetable matter, logs or stones or in the thick coats of animals. Eggs and larval forms are quickly killed by cold or inclement weather, but adult and nymphal ones are remarkably resistant to such changes. Larval nymphal and adult ticks feed during successive years. Larval and nymphal forms pass the virus of infection to adult forms of the same generation, and adult female ticks pass it to their progeny by means of eggs which they lay. Adult ticks infect one another during the act of copulation. Infection from eggs is carried by larval and nymphal forms of that generation.

Transmission of tick fever by species other than wood ticks is apparently possible. By making modifications for altered life cycles and host habits of other types, maintenance of the disease is explained wherever it exists. At least eight other species have been incriminated. It is known that they serve as carriers of the infection in nature or both as carriers and transmitters of it to human beings. The potentialities of the majority of them with the exception of *Dermacentor variabilis*, the common dog tick, are not completely understood. As ticks are widely distributed in nature, for every section of the country where tick fever has made its appearance native species have been isolated and their potentialities partially identified.²

The gross or macroscopic findings detected in those who have succumbed to tick fever are neither numerous nor distinctive. The petechial eruption persists after death, and an early rigor mortis sets in. The muscles are normal. The skin demonstrates subcutaneous hemorrhages. Gangrene may be present, commonly affecting the scrotum, faucial pillars or soft palate. The peritoneal, pleural and pericardial cavities are normal. The lungs show hypostasis. Occasionally bronchopneumonia is found. The heart may have hemorrhages into the pericardium. The right side is distended with blood, the left side contracted. No lesions of the aorta, vena cava or large vessels of the extremities or trunk are found. The spleen is enlarged, being soft or firm in consistency. The liver demonstrates fatty changes. It is enlarged and pale, and injection is apparent. There is stasis of bile in the ducts. There are no gastrointestinal lesions. Pancreatic enlargement may exist. The kidneys are at times enlarged, being injected and degenerated or fatty. There may be injection of the renal capsules and all serous membranes. The uterus and bladder show no lesions. The lymph nodes are usually enlarged. Central nervous system lesions consist mainly of injection of the meningeal blood vessels.

Microscopic findings are more typical. Certain variations are said to exist between eastern and western forms of the disease, to which the interested reader is

referred for further study. The alterations typical of the disease are found in the blood vessels of the skin, subcutaneous tissues, testes and appendages. Blood vessels of the skeletal muscles are spared. Early vascular lesions consist of proliferations of the vascular endothelium accompanied by infiltration of the vessel walls with mononuclear cells and polymorphonuclear leukocytes. Thrombus formation follows degeneration of the proliferated endothelium. There are heavy perivascular accumulations of mononuclear cells, presumably of endothelial origin. The endothelial reaction, followed by necrosis of the small blood vessels of the skin is the mechanism of cutaneous and subcutaneous hemorrhages. Other features of the rash are explained by the occurrence of occluding thrombi in small arteries and veins. The changes brought about by the disease are so typical that tick fever may well be called a condition of the peripheral blood vessels or an acute specific endangitis.

The minute causative micro-organism may be demonstrated with considerable difficulty in the blood vessel walls in the endothelium and smooth muscle fibers of the media in relationship to thrombi. Vascular and diffuse cellular lesions and focal necrosis of the heart muscle and at times lesions of the vasa vasorum of the aorta are found. Capillary and sinus thrombosis and focal necrosis of the liver and spleen occur, accompanied by reticulum cell swelling. The spleen shows pronounced engorgement, there being extensive phagocytosis of red blood cells. The lymphoid tissue is decreased in amount. A reticulum macrophage reaction occurs in the lymph nodes which may terminate in necrosis. Adrenal alterations are either slight or absent. The accumulation of endothelial cells in the blood vessels of all organs including the gastrointestinal tract indicates the general reaction to the disease. No particular lesions of the central nervous system are recorded.³

Tick fever has a usual incubation period of from four to eight days, the extremes being two to twelve. The prodromal manifestations resemble those of any febrile illness, there being malaise, headache, anorexia and chilly sensations. They vary in degree, lasting an average of two or three days.

The disease usually has abrupt onset, initial symptoms often appearing in the late afternoon or early evening. There is a definite chill, pronounced frontal headache and severe aches and pains in the muscles, bones and joints. The latter are more pronounced in the back and lower extremities. Firm pressure over the calf muscles or free motion of them often elicits pain. Crawling or attached ticks are sometimes detected on inspection of the patient. Although none are usually found, indurated sites of former attachment may be palpated. Inspection of the bite areas reveals nothing unusual with the exception of occasional discolorations from subcutaneous blood extravasation. The regional lymph nodes are at times palpable and tender.

There may be an initial elevated macular rose colored eruption, similar to that common in measles. Its presence is not distinctive. The petechial eruption first appears on the wrists and ankles twenty-four to

forty-eight hours after the onset of tick fever. It is the most reliable early manifestation of the disease. It may be overlooked in individuals of dark skinned races or ones much tanned on the extremities from overexposure to the elements. It soon becomes sharply perceptible and spreads from the initial locations in a centripetal fashion over the chest and abdomen and thence to the remainder of the body (figs 1 and 2). It is always more pronounced on the extremities than elsewhere. Extension is complete in two or three days. The associated generalized aches are then relieved to a degree, but the temperature remains high. The petechial eruption is thought to be the most characteristic finding in tick fever, but diagnosis of the disease must not be made on its presence. Some patients, particularly those only mildly affected or those previously vaccinated, never show a rash or have an insignificant one; others die before its appearance from toxemia, and yet others demonstrate atypical or bizarre eruptions. Petechiae do not disappear on pressure except during the initial stages of tick fever. They are accentuated by tourniquet application. They may eventually involve the palms of the hands, soles of the feet and mucosa of the inner cheeks and throat. A patient so erupted is truly spotted or speckled, having a rash which covers the entire body. Petechiae may appear in successive crops each of which has an average life cycle of two weeks.

The eruption tends to remain discrete in milder cases of tick fever. It is first rose red and later bluish red. Discreteness does not persist in more severe ones. The petechiae increase in size and become confluent, finally coalescing and then becoming purpuric. A mass of such areas may involve the entire body. If terminal gangrene ensues, with sloughing of the soft palate, scrotum or other dependent portions of the body, the afflicted person presents a tragic appearance (figs 3 and 4).

The petechial eruption gradually fades as patients recover. Fading takes much longer in severe cases than in mild ones. It occurs with the fall in temperature. There may be desquamation, either branlike in character or so complete that casts of body parts are

Fig 1—Petechial eruption on upper extremities during early stages of Rocky Mountain spotted fever. The original sites were on the wrists but extension to the hands and lower arm regions has begun.

exfoliated. Pigmentation remains at former petechial sites. It may be followed by formation of minute cicatrices. For several months following recovery from tick fever, overexposure to heat or cold often brings out temporary manifestations of the eruption. They last only a short while and clear when the skin temperatures again return to normal.

Temperature rises abruptly within the first twenty-four hours of the onset of the disease. There are but one or two slight remissions, a fastigium of 103 to 105 F being reached by the beginning of the second week in mild cases, by the second or third day in more severe ones. With recovery from acute manifestations

Fig 2—Petechial eruption following extension over the body. The lesions remain discrete but are well distributed over the arms, chest and abdomen.

of the illness, it falls either by rapid or by slow lysis rarely by crisis unless the case is an abortive one. There may be slight temperature remissions in mild cases, but it is constant to slightly rising in more severe ones. It is sometimes distinctly remittent after the first few days, particularly in moderately severe protracted cases, but never ceases until terminal lysis has occurred. The temperature may be normal from the first or subnormal in very severe forms of the disease, to rise sharply in the twenty-four hours preceding death, or it may be high from the first, then drop to normal and rise again before death occurs. If the temperature drops uneventfully to normal and later shows a secondary rise without apparent justification, complications must be sought for.

Early in the disease the pulse is of good volume. It is slow, averaging 90 beats a minute. Early disproportion of pulse and temperature ratios is one of the characteristics of tick fever at its onset. When myocardial weakening ensues in severe cases as a result of toxemia, loss of strength and volume of the pulse occurs. It rises out of proportion to the temperature. As a result of cardiac involvement the blood pressure falls and the first heart sound becomes muffled and indistinct.

The respirations are at first normal or but slightly increased. They accelerate in severe cases, with alterations of the pulse and temperature ratio. Increase in rates often signify the development of bronchopneumonia.

The foregoing manifestations are considered to be the most typical ones in tick fever. There are other findings. They exist in various combinations, their intensity often depending on the severity of the existent disease process.

Patients moderately or severely ill with tick fever are severely prostrated. The senses are dulled. Although afflicted persons appear rational to superficial examination, close inspection reveals that they are mentally confused. There is amnesia. It may persist until the eruption is complete or for some time afterward. Patients appear anxious and concerned over their illnesses. The eyes are injected and the cheeks flushed.

There may be photophobia. Nervous disturbances such as lethargy, restlessness or nervous irritability are frequent. Children are prone to convulsions and may die during them. Insomnia is at times troublesome. There can be active delirium, particularly in severe cases during the terminal stages of the illness. Muscular twitchings or fibrillatory tremors are common. Muscle tonus is definitely increased throughout the body. Aches and pains in the muscles persist throughout the disease. At times the distress from them is agonizing. When located in the muscles of the abdomen an acute surgical condition can be simulated. Movement of the neck muscles often elicits slight stiffness.

The tongue is swollen and moist early in the disease. In severe cases it becomes dry and coated with a darkened border and prominent papillae. The tongue often protrudes from the mouth when profound swelling ensues. It becomes fissured and covered by sordes if coma occurs. There is pharyngeal engorgement accompanied by a dry, hacking nonexpectorative cough indicative of bronchial irritation. There is often profound chilliness. It is not shaking or chattering in character but tends to be most persistent and drawn out frequently lasting for a period of from two to four hours.

The skin is tender. Many patients complain bitterly of pressure from light bed coverings or drafts of air. As the disease progresses it becomes dark red or bluish in more severe cases, the color changes being most evident on the back and thighs. An ill defined bluish discoloration is commonly seen beneath the skin surfaces when patients are examined under satisfactory light conditions. Dependent portions of the body such as the scrotum or soft palate may slough in severe cases. Necrosis can occur, commonly affecting the prepuce, toes, fingers or ear lobes. Alopecia sometimes appears. It may be permanent.

There is anorexia. Nausea and vomiting take place in some cases, the regurgitated material at times containing blood. Diarrhea occasionally occurs, the stools may be bloody. Constipation is usual. It can be most obstinate and difficult to overcome. Sphincter control is often lost in severe cases. The spleen is enlarged and tender. The liver sometimes demonstrating similar find-

Fig. 3—Appearance of the right hand in the terminal stages of a fatal case of Rocky Mountain spotted fever. Necrosis of the fingers has begun later eventuating in gangrene. The skin of the dorsum of the member being ichthyoid in character and commencing to exfoliate.

ings. There is jaundice. It is nonobstructive in type and tends to deepen definitely in the terminal fatal stages.

Increased muscle tonus may result in an inability to void urine. At times there is incontinence. Urination can be distinctly painful. A lessened secretion of urine sometimes occurs. It is caused either by changes in the kidneys or by a failing circulation and is frequently

accompanied by edema. There may be total repression of urine formation at the end in fatal cases of tick fever.

The blood findings are not unusual. There is a lowered red blood cell count and hemoglobin content later in the disease, resulting in a secondary anemia. The total white blood cell count averages 12,000 to

Fig. 4—Advanced terminal necrosis of the toes and feet of a fatal case during the final stages of Rocky Mountain spotted fever later eventuating in massive gangrene of the parts.

15,000. It may be as high as 30,000. A relative mononucleosis is common, the average being 10 to 12 per cent.

The urine may be highly colored. There is an increased specific gravity. Old or debilitated persons commonly show albumin in varying amounts, together with acetone bodies and microscopic alterations. Younger persons or those who have previously enjoyed good health do not manifest urinary changes so frequently.

Blood chemistry studies in tick fever have never been conclusively worked out. There are no significant spinal fluid findings. Demonstrations of the causative micro-organism of the disease in blood smears are so inconstant that time and energy expended in search for them is not worth the effort involved.⁴

Tick fever may be confused with various other infections, particularly when the disease appears unexpectedly in a locality or it encountered by those unfamiliar with its manifestations. The diseases most commonly causing confusion are typhoid and allied conditions, severe measles, smallpox, epidemic meningitis, especially of the septicemic variety, undulant fever, streptococcal septicemia, purpura, typhus fever and Colorado mountain fever. It is not within the scope of this paper to discuss the conditions, references being made to them elsewhere. For the most part confusing diseases can be ruled out by careful histories, examinations and repeated observations of the infected persons together

with confirmatory laboratory studies. The three diagnostic procedures ordinarily employed are the infection test, the Weil-Felix agglutination reaction and the protection or virus neutralization test. They are not dealt with in this article. References to them may be found in other papers.¹

Tick fever could be completely eradicated were it possible to dispose of vectors of the disease. The undertaking is an impossible one. Conditions favorable to ticks exist in all localities where the disease is found. These allow hosts for both immature and adult forms to flourish in abundance. Vegetation and physical conditions exert an indirect influence, because they afford suitable surroundings for animals serving as tick hosts. Once established in a locality, ticks continue to thrive if there are sufficient numbers of wild or domestic animals present.

Prevention of exposure to infection is secured only by remaining out of localities where ticks abound. Such precautions are not at all times possible or feasible. Those entering infested localities should wear trousers, gathered by some means at the bottoms in order to prevent vectors from crawling up the legs. Ticks do not jump on those who pass their vantage points but lie in wait on low grass or vegetation not over a foot and a half above the surface of the ground, actively moving their numerous serrated legs, by which means they seek transfer to objects that brush by. Clothing should have a minimum of seams and openings in order to prevent their ingress to body surfaces. Smooth clothes prevent ticks from gaining footholds, yet those with a rough nap impede their progress once they have got on the body covering. It is a good plan while in tick infested localities to pass the hand occasionally over the back of the neck in order to detect crawling ticks. They may gain access to the body by working themselves beneath the collar.

Clothing should be removed at least two or three times a day and the body thoroughly examined for the presence of crawling or attached ticks. As they hide away in body folds, crevices and hairy portions free from rubbing, a diligent search must be conducted. Camps should be located where rodents are few, preferably in places where no low grass, sagebrush or small bushes are growing. Wooded areas along creek banks are best avoided, as are the vicinities of old trails and roads. Ideal camping spots are usually where standing timber is present with a minimum of low vegetation. Persons must again inspect their persons, clothing and bedding before retiring for the night in the open. The precaution is most important when 2 persons sleep in close proximity. Infected ticks may attach themselves to both persons successively. The first one may escape infection or be but mildly ill, the second one more seriously so from reactivation of virus in the tick vector by blood ingestion from the first victim. While in tick infested localities it is unwise to leave bedding spread on the ground during the day. It attracts ticks, often from a considerable distance. After return from trips, clothes and bedding should be carefully gone over, aired and then removed to buildings not used for human habitation. Once ticks have taken up their abode in a location, eradication is apt to prove most difficult and uncertain.

When ticks gain access to the body surfaces they move slowly about for a variable length of time, during which they seek suitable locations for attachment. The process is not noticeable to victims, nor are they usually

aware of crawling ticks. It is supposed that vectors of the disease are not actively infectious until several hours have elapsed, but little reliance can be placed in this contention. When located, attached ticks must be removed without delay. The procedure is one requiring considerable skill and perseverance if it is to be safely accomplished. As a rule the head of the tick is embedded beneath the surface of the skin, the body remaining free and protruding at an angle from it. The head is held firmly in place by mouth parts, so that hasty or careless plucking often serves to remove the body alone, leaving the remainder in place to serve as a potential source of infection. Gentle traction may be successful in removing the tick. Close inspection then reveals it to be intact, often with a small fragment of epidermis caught in the mouth parts. Failing in the procedure, a small piece of epidermis in which the tick's head lies embedded must be elevated with a pair of tweezers and a tentlike wedge of tissue snipped with a fine pair of scissors. The maneuver is accomplished in a matter of seconds and insures complete removal. Resultant wounds from tick extraction by any means are to be thoroughly cauterized by means of phenol, silver nitrate, iodine or similar agents. A light dressing can then be applied. Care must be exercised so as not to crush ticks. If the accident occurs, the discharged contents should be thoroughly washed from the hands by soap and water, care being exercised not to irritate the skin. For the reason that virus is apt to be highly infectious, even on unabraded skin surfaces, precautions for its removal are most important. Removal of engorged ticks with bare hands is a dangerous practice.

Tick vaccine gives protection against tick fever. It is prepared by the Rocky Mountain Laboratory of the National Institute of Health, Division of Infectious Diseases, at Hamilton Mont., and is dispensed to physicians desiring it for the purpose of immunizing those who run the danger of being exposed to the disease. Tick vaccine is made in two types, the older one from tick tissues and the more recent one from embryonic chick tissues. The chick embryo type has not superseded the vaccine prepared from ticks, and, although it is less likely to cause reactions, evidence regarding its immunizing value is not so certain. Recommended dosage of tick tissue vaccine for those who have never previously been vaccinated is 2 cc., repeated at an interval of from seven to ten days. If the particular locality is one in which serious cases of tick fever are known to originate, the second injection must be followed by a third, administered after the same time interval. Children receive a proportionate amount of material, 1 cc. being recommended for those 10 years of age or younger. Dosage of the chick embryo type is slightly different, in that three injections of 1 cc. each, administered at the same time interval, are recommended. For individuals who have been vaccinated each of the past three years, two injections of 1 cc. each of either the chick embryo or tick tissue types are suggested.

The degree of protection afforded by vaccine and the duration of such protection varies with vaccinated persons and the virulence of infection to which they are exposed. As a rule, those vaccinated in the spring of the year retain a considerable degree of immunity for at least the remainder of that year. This is usually sufficient to afford full protection against relatively mild strains of the disease but is progressively less effective as virulence of the virus is increased. Nevertheless

against even the more severe forms of tick fever it is usually adequate to anchorate materially the usual stormy course of the infection so as to insure ultimate recovery. It is probable that a certain proportion of individuals carry an indefinite degree of immunity into the second year even against highly virulent strains

Fig 5—Case fatality rates from Rocky Mountain spotted fever in Wyoming from 1927 to 1942. 1930, 1936 and 1942 were years of high fatality rates. 1927, 1933 and 1939 ones of low fatality rates. There is apparently a definite six year occurrence of high and low rates. (Courtesy Dr. H. Savage, epidemiologist, Wyoming State Health Department.)

of virus. The degree of protection appears to be greater in those who have been vaccinated for two or more successive years. Evidence does not indicate that any considerable degree is carried into the third year. In order to afford the greatest degree of protection possible, it is recommended that immunization be performed each year.

Intramuscular administration of vaccine is not known to bring about more than a slight constitutional reaction. The same precautions must be observed as with the injection of any biologic product intended for an immunization procedure. Immediately there ensues a sensation of numbness at the site, followed by one of smarting or stinging. Itching may occur, exacerbated by scratching or rubbing the part. A generalized malaise sometimes is noticed, often with a slight febrile reaction. The manifestations are usually transitory, subsiding before subsequent administrations of the material. These usually result in much milder symptoms or none at all. Reactions to the use of vaccine have not been so prevalent in recent years. It has been purified and standardized, and of late embryonic chick tissue preparations prepared by the yolk sac method of Cox have been extensively used.⁵

Treatment of tick fever is purely symptomatic and supportive in character. There is no specific. Its absence must not predispose to an attitude of helplessness and hopeless inactivity on the part of those caring for the disease. Carefully directed symptomatic care and supportive measures aid patients to eliminate toxins from their bodies, support them during the period of

invasion and assist them in every means possible. Vigorous yet well directed procedures bring about successful outcomes for many patients whose recovery appears hopeless at the time they are first placed under care.

Bed rest with good nursing care is necessary from the beginning of the illness in order to conserve strength as much as possible. At the onset patients frequently do not appear ill enough to make the precautions necessary, but the rapidity with which serious manifestations appear make those in attendance thankful that they have been insisted on. Patients must be kept as quiet as possible, both mentally and physically. Baths, packs and simple sedation are often effective. If codeine or even morphine is indicated, they must be used as freely as necessary. Bath temperatures should be 70 F or above to be safely tolerated. Cold or tepid bathing often results in shock to seriously ill victims of tick fever.

The gastrointestinal tract needs careful watching. Regular elimination may be facilitated by mild enemas or cathartics. The diet should be nourishing, adequate and easily digestible. Frequent urinary examinations are indicated. They detect pathologic alterations at their onset. Fluids must be freely given by mouth if tolerated. When there is excessive vomiting they may be administered by other routes. Adequate amounts combat the ever present trend to acidosis.

It may be necessary to support the heart should myocardial weakening appear imminent. Care to the skin is important. Equal parts of hamamelis water and alcohol in water applied once or twice a day as a sponge often comforts and invigorates severely ill patients. It removes soreness from muscles and revives them. They are less mentally dulled, appearing stronger for several hours following the procedure. Mouth hygiene is important. Oral antiseptic washes rid the region of accumu-

Fig 6—Cases and deaths by sites of infection for 1940. There were 62 cases of Rocky Mountain spotted fever with ten deaths. Three of the cases were out of state infections, 2 in Montana and 1 in Utah but were reported by Wyoming physicians. (Courtesy Dr. H. Savage, epidemiologist, Wyoming State Health Department.) Symbols on maps: x cases, o in circle deaths, * infected in Wyoming, death in adjoining state.

lated waste products, so that sufferers are made more comfortable during the acute phases of the illness.

Convalescent serums and transfusions have been resorted to, apparently without beneficial effect. Auto-hemotherapy has been used by some physicians, 10 to 20 cc of citrated blood from the patient being read-

Baker, Carey and Duncan, Hutton, Parker. Rocky Mountain Spotted Fever.

administered intramuscularly. The procedure is repeated as often as necessary. Many drugs have from time to time been lauded as specifics in the treatment of tick fever. It is agreed that the action of the majority of them is not certain and for that reason they have been generally discarded. Drugs of the sulfonamide series

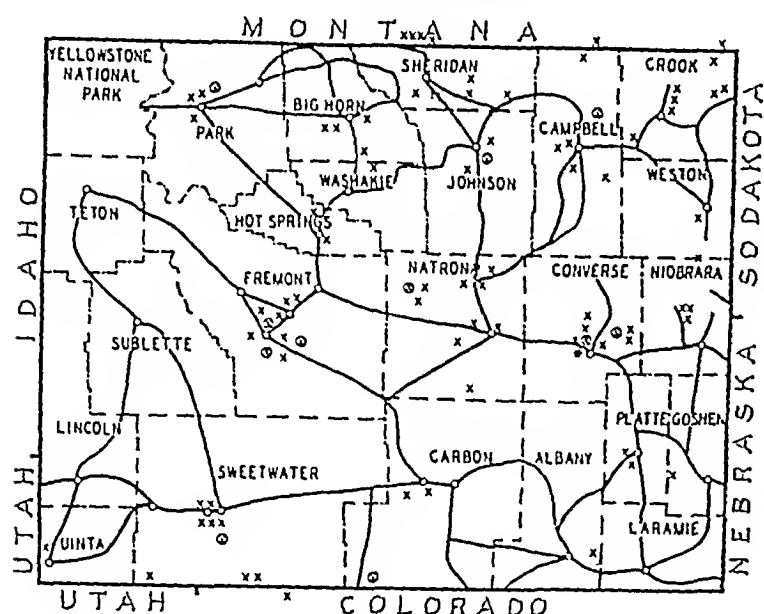

Fig. 7—Cases and deaths from Rocky Mountain spotted fever in Wyoming, by sites of infection for 1941. There were 89 cases with eleven deaths. Seven of the cases were out of state infections, 6 in Montana and 1 in Colorado but were reported by Wyoming physicians. (Courtesy Dr. N. H. Savage, epidemiologist, Wyoming State Health Department.) * Infected in Wyoming, died in Colorado.

have little or no value in the management of tick fever, according to information available on them at this time. If bronchopneumonia, phlebitis or other complications due to secondary invaders appear, their use is certainly justified, the drugs of choice depending on the nature of the invading micro-organisms. Recently Topping has produced an immune serum in rabbits, using tick virus as the antigen. The rabbit serum has been shown to contain large amounts of antibodies. Satisfactory results have been achieved from its use, at first in animal experimentation and later in an increasing number of human beings. Tick vaccine must never be used for treatment. It has no beneficial action when used for this purpose. In milder cases its use is too drastic to be justified, in more severe ones it may prove dangerous as regards ultimate recovery.⁶

Tick fever appears to have a cyclic tendency, more cases appearing during some years than others, the reason for the trend is unknown, but it is believed to depend on local and regional conditions. The number of individuals exposed, the abundance of ticks, the percentage of ticks carrying infection, the capability of virus to produce frank infections and the possible relationship between the prevalence of ticks and animal hosts seem to play a part.

The highest incidence of tick fever in the western area is from the early spring into the early summer months. In the mountainous regions it is highest during the late spring months, owing to delay in the advent of warm weather. In the eastern areas the disease is more prevalent in the late spring and early summer months, but cases can occur in the fall of the year.

6 Carey, L. S., and Duncan, G. G. Rocky Mountain Spotted Fever in the East, J. A. M. A. 110: 175 (Jan. 15) 1938. Clinical Notes Insect Incendiaries, What's New 66: 7, 1943. Hutton, J. G. Rocky Mountain Spotted Fever, J. A. M. A. 117: 413 (Aug. 9) 1941. Topping, N. H. Rocky Mountain Spotted Fever. Treatment of Infected Laborers with Immune Rabbit Serum, Pub. Health Rep. 55: 41 (Jan. 12) 1940. Baker, C. Clinical Notes. Observations. Parker, Rocky Mountain Spotted Fever. Symposium. Rocky Mountain Spotted Fever.

The virulence of tick fever varies greatly in different areas but appears to remain fairly constant in any one region. Reasons for the variance are now known. It is supposed that repeated passages of the virus through successive animal hosts play a part. It is justifiable to speak of mild, moderately severe or severe types of the disease, in view of the great differences in virulence of the infection in various localities and sections of the country.

Practicing medicine in the western endemic area, in a section of Wyoming where tick fever occurs with considerable frequency, I have had occasion to make extensive study of its various aspects. It is possible that the number of individuals stricken with the disease is beginning to show a yearly decrease. Education of the public is a possible explanation for the reduction. Local residents have become aware of the serious potentialities of tick fever. As a result, many of them take very definite precautions in order to avoid infection.

Tick fever in this particular locality is moderately severe to severe in type. Seldom is one of mild intensity seen. As fatalities from the disease closely parallel in number the severity of existent infections, deaths must be expected. For a period of time from 1927 to 1942, during which accurate statistics on tick fever have been kept by the Wyoming State Health Department the average mortality for our (Natrona) county has been 20 per cent. During the same time interval the average for the entire state has been 19.5 per cent. As it is believed that the mortality from the disease for the United States is in the vicinity of 12.5 per cent both local figures are considerably higher than those for the nation as a whole (figs. 5, 6, 7, 8 and 9).

Tick fever has always demanded earnest consideration from members of the local medical profession, residents in the community and surrounding rural areas. For a period of the past fifteen years every fifth person who has contracted the disease has succumbed to it. Symptomatic and supportive measures offer much in treatment, but unfortunately they are not sufficient in

Fig. 8—Cases and deaths from 1942 by sites of infection. There were 36 cases of Rocky Mountain spotted fever with 9 deaths. Two of the cases were out of state infections, 1 in Montana and 1 in South Dakota but were reported and treated by Wyoming physicians. (Courtesy Dr. N. H. Savage, epidemiologist, Wyoming State Health Department.)

themselves to insure recovery. Prognosis in the ultimate depends on the ability of infected persons to withstand ravages of the disease, particularly in reference to myocardial and renal intoxication. Bad omens are those of a confluent purpuric eruption with terminal

sloughing, definite temperature and pulse reactions, severe intoxication of the brain and central nervous system, and the development of complications, particularly in older or debilitated persons or those ill with intercurrent conditions.

In 1934 the late Dr J C Kamp of Casper and I began original investigations on the use of neosarsphenamine dissolved in aqueous metaphen solution administered intravenously. We had previously received encouraging reports of responses obtained by use of the two drugs in combination for treatment of typhus fever. That year we used them in 9 moderately severe cases of tick fever without any deaths from the illness. Response was so gratifying that we decided to administer neosarsphenamine in metaphen in the future as a routine measure in all cases which came under our supervision.

Since that time an average of 3 to 4 cases of the disease have been under my care each season. During the past eight years all those so treated have recovered. Local physicians and ones practicing in other sections of the state have used the two drugs in combination as an adjunct to care for individuals seen by them. Those whom I have communicated with report equally gratifying responses, many of them joining in the firm conviction that neosarsphenamine in metaphen solution is a definite therapeutic aid in treatment of tick fever.

It is not thought that they exert a specific action on manifestations of the disease. Their approach is admittedly uncertain. Benefits derived from their use may be credited to direct action on rickettsias in the tissues. They can be attributable to a combination of the bactericidal action of metaphen together with the spirocheticidal action of neosarsphenamine on a microorganism which is bacterium-like in character yet has staining properties similar at least to those displayed by spirochetes. It is certain that those treated show less evidence of intoxication, minimal damage of the heart and kidneys and a more discrete, brighter colored eruption. The rash does not become hemorrhagic and is usually more sparse in distribution. There are less mental depression and milder nervous symptoms. In fact, the entire clinical picture is less alarming. Convalescence is more rapidly established, being of shorter duration with a minimum of complications. None of the patients had received tick vaccine for the purpose of immunization against the disease.

In the performance of the procedure 0.3 Gm. of neosarsphenamine is dissolved thoroughly in 10 cc. of an aqueous 1:1000 metaphen solution. The resultant yellow and turbid mixture changes but little on standing. It is warmed and injected slowly by vein, the same precautions being observed as with any chemotherapeutic agent intended for intravenous administration. Solution is administered and blood alternately withdrawn into the syringe until the entire amount has been given. The procedure usually consumes a period of five to ten minutes. No reactions local or constitutional, either immediate or delayed, have thus far been observed.

Administration of the two drugs is repeated at three to four day intervals. Three or four injections have customarily been sufficient to ameliorate the clinical picture so as to insure ultimate recovery. Continued or recurrent manifestations would apparently justify additional administration of neosarsphenamine in metaphen solution.

A word of warning appears indicated to those who might contemplate use of the two drugs in combination for treatment of tick fever. Should a case of the disease demonstrate severe renal injury as a result of the infection, careful consideration must then be given to the question as to whether or not their use is justified. The inherent risks associated with drugs of considerable potency on an already damaged kidney must be weighed against benefits to be derived from their administration. It has been my custom to secure first morning specimens of urine for examination on the day the material is to be given. These have never shown sufficient alterations

Beginning with 1940 all cases and deaths have been allocated to the county or adjoining state where the infection occurred. This gives a more accurate picture of the attack and fatality rates for each county and eliminates out of state infections. Prior to 1937 all cases were assigned to the counties reporting regardless of the site of infection. (Courtesy of Dr N H Savage epidemiologist Wyoming State Health Department.)

One Converse County 1941 death and one Weston County 1940 death occurred out of the state but the infections occurred in Wyoming.

to suggest severe renal disease. For that reason neosarsphenamine in metaphen solution has routinely been given at the time scheduled for its use.

Detailed discussion of several cases of tick fever serves no useful purpose. The majority of them demonstrate clinical manifestations similar to what has been given in the preceding pages. A few have been selected for brief presentation, as they are sufficiently interesting or unusual to emphasize important features of the disease.

REPORT OF CASES

A middle aged rancher and his wife (J D) seen in February 1933 were ill with tick fever. Even though attached ticks were found on both patients at the time they were first examined and complete eruptions had occurred we were at a loss to explain the source of infection. The weather was extremely cold and the ground covered by several inches of snow. Their residence was a single room house heated by a kerosene burner. Examination of a sheep-skin coat which hung behind the stove revealed it to have several dormant wood ticks deeply hidden

in the wool lining. The coat had been worn the spring before by another person engaged in lambing activities. It had later been brought to town and discarded in the place where it was later found, being so old and worn out as to be nearly forgotten. It is assumed that artificial heat created by the stove had released tick vectors from hibernation in the coat. They had been aroused from a dormant state and had easily found human hosts. One patient was more ill than the other, but both recovered. It is assumed that in infected tick or ticks had in some manner been reactivated, in feeding on successive hosts or incubation by warmth from the fire burner, either of which would have predisposed to increased virulence in vectors of the disease. As a result one of the infected persons was stricken with a severe type of tick fever.

R S, a middle aged shepherd, seen during May 1940, was ill with tick fever, moderately severe in type. The patient had been in Wyoming a month, coming to the state from Pennsylvania, where he had farmed for several years. Prior to becoming ill he had found numerous crawling and attached ticks on his person. They caused him no concern and were carelessly plucked off. On being advised as to the nature of his illness and the manner in which it had been contracted, the patient became most disgruntled, stating that ticks which attached to human beings were common in many sections of the state where he had formerly resided. They were not considered dangerous. To his knowledge no one had ever developed an illness simulating the one he was diagnosed as having. An attached wood tick was detected in the left axilla, deeply hidden by the hair. The tick was removed and shown to the patient. Following careful inspection of it he agreed that those with which he was familiar in Pennsylvania were not wood ticks but ones of another species. The patient made an uneventful recovery. Following discharge from the hospital he left immediately for home and never again returned to Wyoming.

O W, a young housewife, reported for care in May 1941. Her complaints were those of headache and generalized malaise. An attached wood tick was found on the right shin. It was removed and symptomatic measures were instituted. Two days later she was seen again, at that time being quite ill. A beginning petechial eruption was noted on the wrists and ankles, the associated manifestations being those of moderately severe tick fever. The patient consistently denied having been in rural areas before the onset of her illness, stating that she had not left her home for a period of several weeks prior to becoming ill. Her husband was a fishing enthusiast. He had made several trips into tick infested localities, it being a custom for him to place his outing clothes on a line in the yard when returning home. It is believed that he had brought ticks to town with him. As the same line was used by the patient to hang the family washing, it is assumed that an infected tick had dropped to the grass beneath the line and had later attached itself to her. The husband of the patient had routinely been immunized against the disease each spring. She had refused vaccination, as fishing and outdoor activities did not interest her. For that reason she did not feel the precaution to be necessary.

S F, an elderly rancher, was seen in May 1941 suffering from a moderately severe type of tick fever. Although a complete eruption was present at the time he was first seen, he stoutly maintained that he could not have the disease. He had ranched in the same locality for a period of forty-five years. Never having gotten tick fever, it was his assumption that he was immune to it. As serious manifestations from the illness developed rapidly, persuasion was not difficult. The prognosis was guarded because of his age and of a past history of chronic alcoholism. He developed a complicating bronchopneumonia but recovered following a prolonged and stormy illness. During its acute stages he was mentally confused and often irrational. A brother from whom he had been estranged for several years, realizing the seriousness of the patient's condition and believing him about to die, attempted to bring about an alteration in his will. Had his plan been successful the unscrupulous rascal would have inherited a large sum of money, leaving the patient's wife and children in a destitute state. Legal intervention prevented the misdeed. Following recovery and having no recollection of what had transpired,

the patient was most disconcerted to learn that he had agreed to the unreasonable alteration. He was finally convinced that the confusional state existent during the acute stages of his illness was responsible for the errors in judgment shown by him at the time.

SUMMARY AND CONCLUSIONS

Rocky Mountain spotted fever (tick fever) is wide spread in distribution throughout the country. It has possibilities for far greater dissemination, being a disease of serious potentialities. The clinical picture is fairly typical. There is a possibility of confusion with other disease states. Prevention of infection may be secured by simple precautions and the use of tick fever vaccine. Treatment is essentially symptomatic and supportive. Neoarsphenamine dissolved in aqueous metaphen solution has been used intravenously as an adjunct to treatment. Satisfactory results have been obtained in a number of cases so treated over a period of the past eight years. It is believed that the two drugs in combination exert a definite beneficial action on the course of moderately severe cases of the disease.

226 East Second Street

HISTAMINE IN THE TREATMENT OF MÉNIÈRE'S SYNDROME

JOHN J. RAINEY, M.D.

TROY, N. Y.

This paper is concerned with the results obtained by the intravenous use of histamine phosphate in patients who are the victims of the symptom complex called Meniere's syndrome. As none of our patients came from a distance it was possible to follow the results obtained by each patient from the first day of treatment up to the present time. Since December 1940 we have treated 22 patients with Ménière's syndrome by means of histamine phosphate intravenously. Seventeen of these patients had striking results and at present all are well and going about their daily tasks. With 5 patients our results were disappointing. Only 1 of these 5 patients had had a major attack. These 5 patients have agreed to further study. Among our patients women predominated, and the ages varied from 40 to 76.

Ménière's syndrome is the name given to a group of symptoms in which vertigo, nerve deafness and tinnitus predominate. The nerve deafness may be either unilateral or bilateral and the loss of hearing is variable, ranging from slight diminution to total deafness. Most of the attacks of vertigo occur without previous warning and often are terrifying in their intensity. The attacks may be accompanied by nausea and vomiting. In most instances objects whirl about the patient or the patient rotates about the objects. He may fall suddenly to the ground or, if in bed, he grasps the sides, as he has the sensation of being thrown to the floor. However, the attacks of vertigo may occur without deafness or tinnitus. Some patients, indeed, have an ever present mild vertigo that in most instances has been preceded by major attacks.

It is generally accepted that the symptoms of Meniere's syndrome are the result of a local disturbance of the inner ear. Horton¹ believes that the most likely

Read before the Eastern New York Eye, Ear, Nose & Throat Association, Albany, N. Y., Oct. 1, 1942.
1. Horton B. T. The Use of Histamine in Meniere's Disease. *Gynec. & Obst.* 72: 417-420 (Feb. 13) 1941.

causative factor is local alteration in the permeability of the capillary wall of the labyrinth resulting in local edema. Dale proposed several years ago that, when the particular foreign substance to which man or animal is hypersensitive comes in contact with its specific antibody in the tissue cells, histamine is released. Histamine in turn causes smooth muscle spasm and localized edema which are the lesions of anaphylaxis and allergy.² It follows that the intravenous use of histamine results in desensitization and amelioration of the symptom complex.

In 1861 Meniere, a French physician described the disease, and nothing as far as the symptoms are concerned has been added to his original observations. Meniere reported the history of a young woman who spent the night riding on top of a stagecoach exposed to a cold drizzling rain. She contracted a severe cold that was accompanied by persistent vertigo, deafness and vomiting, the vertigo and vomiting being aggravated by any movement of the body. After five days of illness the girl died. At necropsy a bloody exudate was found in the semicircular canals.

This was before Pasteur established the bacterial origin of disease, so Meniere incorrectly concluded that his patient's death was due to hemorrhage within the semicircular canals. We know now that the girl died of purulent labyrinthitis.

We can trace Meniere's syndrome back to antiquity. One of the best medical writers of the twelfth century was a Benedictine abess, later canonized Saint Hildegard. She considered vertigo as being caused by a congested condition of the brain. "When headache and vertigo attack a patient simultaneously," she observes, "they render a man foolish and upset his reason." Martin Luther, while an Augustinian monk, suffered from attacks. During his career as a reformer occurred the scene in which he threw the inkwell at the devil who was roaring in his ears. Dean Swift, the great satirist, also was afflicted and carefully recorded his own symptoms. Never a pleasant man, he turned violently sour the latter part of his life because of the frequency of the attacks and lived in seclusion. Beethoven was afflicted with bilateral nerve deafness. It is probable that the rages to which that great man was subjected were brought on by attacks of Meniere's syndrome. The first movement of the fifth symphony is highly suggestive. It is a matter for conjecture—the effect on that great genius if he had had a bilateral resection of the auditory nerve performed. Our own Gamaliel Bradford, noted for his character studies was also afflicted. He described vividly his symptoms as "the swoop of the hawk."

Alexander of St. Louis was the first to report the intravenous use of histamine for chronic urticaria. Horton of the Mayo Clinic, encouraged by Alexander's success, treated a patient suffering from Meniere's syndrome with the intravenous use of histamine late in 1939.¹

The technic for treating these patients is as follows. One cc of histamine phosphate 2.75 mg is diluted in 250 cc of isotonic solution of sodium chloride. This is given drop by drop. In the beginning we gave 60 drops to the minute, and the time required for the treatment was about one and one-half hours. At the present time we are giving 70 drops to the minute. Two patients, however, could tolerate only 40 to 50

drops a minute. Many patients complain at first of constriction of the chest, and to be on the safe side in the beginning we never give more than 20 or 30 drops a minute for the first five minutes. Occipital headache is complained of quite early, but in a short time the pain leaves the occipital region and is confined to the frontal region. At first the face is flushed and within fifteen or twenty minutes the erythema spreads to the chest, the thighs and in some instances the soles of the feet and the toes. By the time the patient returns to his room the flush has disappeared. The blood pressure is determined every ten minutes. With most patients there is a considerable variation.

CASE 1—A woman aged 73, the first patient we treated, first seen by us in August 1940, had had several major attacks of Meniere's syndrome. Ammonium chloride and a salt free diet were advised. Five weeks after her visit she had two major attacks. She then summoned her family physician, who in turn called in a general surgeon. Her gallbladder was removed. Eight weeks after the gallbladder operation she suffered several major attacks. Following these attacks she consulted us again. She entered the Troy Hospital in December 1940. Histamine was given intravenously, and later several subcutaneous injections of 1 cc of histamine phosphate 0.275 mg were given at the office. She has been free from attacks ever since.

CASE 2—An Italian woman aged 52 had a severe major attack of the syndrome at about 4 one morning in July 1941. The attack lasted several hours. She also had diabetes, which was controlled with insulin. After three weeks of dizzy spells and spending most of her time in bed she entered the hospital and was treated with histamine intravenously. She was given 1 cc of histamine phosphate 0.275 mg subcutaneously twice a week for four weeks. She had had no return of Meniere's syndrome.

CASE 3—A woman aged 62 had several major attacks of Meniere's syndrome in May 1941. The attacks lasted about four hours and the vomiting was severe. The attacks occurred in the early morning hours. She was given several subcutaneous injections of histamine without effect. Intravenous therapy was suggested but was not acceptable at this time.

The patient had a slight enlargement of the thyroid, and, as she had been advised several years before to have it removed, it was decided to have a thyroidectomy performed at the Albany Hospital. Three or four days before operation, and while at the hospital, she had a major attack of the syndrome. Oxygen was given over a period of several hours, but it was of no benefit. She was operated on and had no further attacks until she returned home. The attacks began and histamine was given subcutaneously. The vertigo was not controlled. We treated her intravenously at the Troy Hospital and she remained free from attacks for seven weeks. The attacks recurred and she returned to the hospital for intravenous therapy and remained free from attacks for three months. She then began to have some slight vertigo and after histamine was given subcutaneously all symptoms disappeared. When the attacks first occurred she weighed 108 pounds (49 Kg). Today she weighs 120 pounds (54.4 Kg) and has had no further attacks.

The following case is of interest from a medicolegal standpoint.

CASE 4—In May 1941 a glazier was working on a scaffold in a new building. Through the carelessness of another workman he was knocked to the pavement striking his head. The blow rendered him unconscious. He regained consciousness after several hours but had a constant vertigo aggravated on movement. X-ray examinations for fracture of the skull were negative. He was discharged from the hospital after three weeks but was still dizzy and somewhat deaf.

We saw him almost three months after his accident. He had a staggering gait and had a tendency to lurch to the left, the side injured. He never left the house unless accompanied

2. Alexander H. L. Treatment of Allergic Disorders with Histamine and Histaminase. *J. Lab. & Clin. Med.* 26: 110-116 (Oct.) 1940.

by his wife. We felt that the primary cause of his symptoms was a fracture through the petrous bone.

The lawyers for the insurance company refused settlement.

He entered the Troy Hospital on July 23, 1941 and was given histamine intravenously. He was considerably improved and could walk to the bathroom unaccompanied. He was given another intravenous injection a few days later.

He was given histamine subcutaneously and was symptom free for six weeks. A friend took him for a motor ride, and while walking from the car to the house he fell to the ground. He had a major attack that lasted about one-half hour. He was given another intravenous injection at the Troy Hospital. The subcutaneous injections were maintained for several weeks. Since early in September 1941 he has had no attacks.

In October, one month after he was free from any symptoms, his case was called. The lawyers who previously would not settle for any amount, reinforced by lawyers from New York, who evidently had done some reading on Meniere's syndrome, decided to settle with our patient before the case went before a jury. Our patient received \$15,500.

The last 2 cases are presented for comparison because patient 5 for years has been allergic to extrinsic irritants and patient 6 at no time ever has had symptoms even remotely associated with a reaction from any extrinsic irritant.

CASE 5—A woman aged 62 was unable as a child to participate in winter sports because of a blanching and numbness of the hands and feet. In recent years she no longer had had involvement of the feet, the symptoms being confined to the fingers of both hands. She has always been careful not to place her hands in cold water because of the severe reaction. During the cold months she wore woolen gloves and carried a muff but in spite of these precautions when she returned home she found it necessary to immerse the hands in warm water to restore the circulation. For hours afterward she could not hold a pencil or pen to write. For the past six years she has had attacks of erythema confined generally to the calves of the legs. There were present patches of variable size which caused intense itching. This symptom developed early in the fall and lasted until warm weather. She also was afflicted with vasomotor rhinitis and seasonal hay fever.

When the patient was 18 years of age a physician in Troy diagnosed her condition as Raynaud's disease, for which he was treating her father at the same time. Twenty-five years ago the patient noticed a slight unsteadiness in gait. Glasses were prescribed but they gave no relief. About ten years ago she became aware of tinnitus in the right ear and two years later noticed a loss of hearing in that ear. About six years ago the vertigo which had annoyed her for many years became aggravated, so much so that the patient's husband often found it necessary to accompany her when she went shopping.

In 1938 the patient had three major attacks of Meniere's syndrome accompanied by nausea and vomiting. The first attack lasted four hours and the other attacks about two hours each. After the major attacks the patient discovered that she could not walk a straight line. She had never been free from the sensation of light-headedness but now had a dread of being alone on the streets, especially at street crossings. After arising in the morning it was an hour or two before her equilibrium was restored enough so that she could go about her household duties. She consulted us three years ago because of the vertigo. Nerve deafness of the right ear was found. There was an annoying tinnitus of the right ear. Various forms of treatment that have been suggested during the past several years were tried, but little or no benefit was obtained. The patient was given histamine intravenously on March 18, 1941 at the Troy Hospital. For several weeks she was given a maintenance dose three times a week.

She remained symptom free until Dec. 16, 1942, when she had a very serious major attack that lasted several hours. She felt weak and quite unsteady after this attack. She was given an intravenous treatment of histamine on December 28. This was followed by histamine subcutaneously three times a week. She is no longer dizzy or unsteady and is going about her

duties as well as ever. Her major attack was preceded by an almost unbearable roaring in her right ear. The roaring has stopped.

CASE 6—A woman aged 52 has had roaring noises in both ears for the past six years. At times she had attacks of vertigo. In November 1942 she began to have frequent attacks of vertigo, nausea and vomiting and was a patient in the hospitals of her city for complete examinations. She was advised to have a resection of the vestibular nerve. Her attacks grew more frequent and more severe. About every other day she would have two or three attacks of the syndrome, until she was near exhaustion.

When she entered the Troy Hospital on Jan. 1, 1943 she had no attacks, but about 8 a. m. on January 2 a major attack developed which was accompanied by a severe, spontaneous nystagmus to the left, directed to the more affected side.

When the intravenous treatment was begun the patient immediately had a flushing of the face. Most patients complain at first of occipital pain and a constriction of the chest, but this patient had neither. At first the nystagmus was exaggerated but in twenty minutes it had lessened. At no time did she have dryness of the nose and throat, a common complaint of our patients.

After thirty minutes of medication the flush left the face and body and the nystagmus was apparent only when the patient looked to the left. There was very little vertigo except when the patient turned her head to the left. When she left the operating room all symptoms had disappeared.

The next day the patient attempted to go to the bathroom unaccompanied and had to grasp the bed to save herself from falling. She had no symptoms after getting into bed and enjoyed her meals. On the following morning the patient was given another intravenous treatment. This time she reacted in the usual manner, to intravenous therapy. The erythema of the face and body and other reactions were about the same as those described in the beginning of this paper. There was, however, very little variation in blood pressure. At the present time the patient is back at work and is free from all symptoms.

COMMENT

In the light of our experience with the last 2 patients in particular and with our other cases in general, we have come to the conclusion that one intravenous treatment for Meniere's syndrome is not sufficient. One should give at least two intravenous treatments and in some cases three on alternating days.

Horton,¹ to whom we are indebted for this new form of therapy, lays stress on the subcutaneous maintenance dose. Our experience, however, has placed considerable doubt as to the therapeutic value of the maintenance dose. It is possible that we shall get to rely on the intravenous therapy exclusively.

Alexander² conservatively states that "there have been no confirmatory reports regarding Horton's work."

It is hoped that this report may make some positive contribution to this new therapy for Meniere's syndrome.

CONCLUSIONS

We know that many patients with Meniere's syndrome get well without treatment. Some patients may have intervals of ten or twenty years between attacks. Various forms of treatment such as sedatives, aminium chloride, salt free diet and catheterization of the eustachian tubes often help. On the other hand, the major attacks are terrifying, and the lesser symptoms such as the ever present giddiness and nausea are a physical and mental handicap to the otherwise healthy patient. If our diagnosis of Meniere's syndrome is correct, there is in histamine therapy the most promising method of treatment up to the present time.
